"When I was last in London, I saw for a moment, but had no time to examine, a couple of stereoscopic slides which took in a much greater field than any I had previously seen. I was told that they had been exhibited in the Crystal Palace Photographic Exhibition a couple of months since, and that they and the stereoscope were the productions of a French maker of lenses and photographic apparatus. If they are really successful, and give with equal brilliancy and stereoscopic effect, as the Wheatstone Brewster stereoscope does, pictures including a much wider angle than the old stereoscopic pictures, it would be worth while to give some information concerning them. If I had possessed time I would have called on you and suggested that you might deal with the subject in the JOURNAL, and complete what you have already written on the subject. Should you do anything of the kind, it would be desirable to know something, not only of the principle of construction, but the name of the maker and the cost of the stereoscope and the relative slides."

There are two things implied in the foregoing; first, the embracing of a large angle of view in the picture, and, secondly, the means of examining such picture so that it shall approve itself to the spectator as embracing that large angle—in short, that it shall be panoramic.

The first is easy of attainment. It only suffices that the view be taken by a lens of short focus, which, by being well diaphragmed down, or otherwise, shall delineate the whole field covered in perfect sharpness, or such sharpness as shall display no falling off towards the margins when viewed by moderately high-power eyepieces. And here arises the question, What is a short-focus lens, and what is a wide-angle? Let us assume that the area of delineation—the size the picture is to be, when trimmed—is two and three-quarter inches wide, and this is quite wide enough for every purpose; then to include an angle of view of, say, fifty degrees, the focus of the lens employed must be just a trifle over that of the dimensions given, which focus is, in our estimation, much too short for any save very special purposes. This focus of lens has nothing to do with the dimensions of the plate that is to contain the subject, but only with the amount of subject that may be crammed into a given space, which we have stated should be two and three-quarter inches, although this may, on occasion, be exceeded just a little, which it should not ordinarily be if the centres of the binocular pair are to be the maximum of three inches apart when properly mounted.

But the general panoramic perception of a stereoscopic picture is more dependent upon the focus of the lens through which it is examined than upon that by which it was taken. The perfection of a stereoscope for imparting the idea of magnitude or angular extension to the subject on the slide lies in

the lenses which form the eyepieces being of short focus and achromatised.

When writing the articles on *Stereoscopic Photography* which appeared in the ALMANAC for 1887 we spoke in terms of the highest approval of achromatic eyepieces of six inches focus. We have since then had a stereoscope constructed with lenses of five inches, mounted as then directed, and find this a great improvement in the rendering of the combined pictures on a scale of apparent great magnitude, conveying quite the idea of a panorama even when the pictures were taken by lenses having foci of five and six inches.

We have not seen the pictures to which reference is made in Sir James D. Marwick's letter, but from our own experience we know that in the foregoing remarks we have covered the ground.

IRREGULAR TONING OF GELATINE TRANSPARENCIES.

WE have received a letter from a correspondent detailing a peculiar case of irregularity of action upon a gelatine film which, though not, perhaps, a very common occurrence, is sufficiently typical in its character to bear repetition in these columns with the view of suggesting a possible explanation of other similar mysteries.

In our issue of November 16 last we described, in the course of an article on *Toning Transparencies*, a method based upon the bleaching of the developed image with mercuric chloride, followed, after due washing, by treatment with sulphide of potassium, a plan which, in our hands, has produced most pleasing results, both in gelatine and collodion films. Our correspondent, however, though following implicitly the instructions we gave, has not succeeded, and thus describes his method and his results :—

He says, "I used —'s lantern plates, and I followed your instructions to the letter in developing, fixing, and washing. After the long washing following the fixing the plates showed signs of frilling, although they were passed through a chromo alum bath. After this last long washing I proceeded to bleach the image in the chloride of mercury and chloride of ammonium bath made according to your formula. It took, at least, ten minutes to bleach, or rather whiten. I then washed the plate for half an hour, after which it was placed in the toning solution, consisting of twenty-five grains of sulphide of potassium (commercial) to the ounce of water. The high lights instantly turned blue, while the deep shadows remained white for a long time, at least a quarter of an hour, when they became black, not blue. I should say the transparency was very dense before

it went into this bath. As soon as the white had disappeared I proceeded to wash the plate, when I saw at once that it was doomed. The film commenced to swell in zig-zag lines, about one-eighth of an inch wide, all over the plate, and I could follow these lines forming all over like worms, and in about a minute the film was off the plate."

Such are the plain facts of the case, and at first sight it does not seem easy to point to the cause of the trouble, which does not appear to have been an isolated case, but to have followed every repetition of the treatment. Looking at all the circumstances, however, and comparing them with kindred phenomena, noticed in our own previous experience, we make the suggestion that the abnormal behaviour arises from purely physical causes connected with the gelatine films themselves, and which we will try to explain and follow throughout their course.

The particular plates mentioned by our correspondent are, we know, pretty heavily treated with chrome alum, as a preventative of "frilling." Now, in the first place, though a film may be so treated as to render it insoluble, it does not necessarily follow that it will not frill. On the contrary, if the insolubilising action be carried too far, the film may possibly have its tendency to leave the glass actually increased, for such treatment causes a shrinkage or contraction of the gelatine, which is quite as powerful an inducement to loosening from its support as is the more common fault of swelling. Hence we need not be surprised at these particular plates frilling, especially after an extra dose of chrome alum.

Next, we have the length of time occupied in bleaching. This is only the natural consequence of the ultra hardness of the gelatine itself, coupled with the additional fact of a very dense image (as we are told), which naturally adds to the impermeability. The bleaching solution, chloride of mercury, still further adds to the hardness of the gelatine, and still further clogs its pores by the deposition of subchloride of mercury side by side with the silver-formed image, so that it is scarcely surprising that the toning solution should act with even greater slowness than the bleaching liquid. That this is the true explanation of the irregularity is partly proved by the recorded fact that the high lights, which represent but a scanty deposit and a comparatively porous film, were toned instantly to a blue colour—over toned in fact—while the deep shadows resisted the toning action for a quarter of an hour, owing to the dense mass of material to be acted upon and its closer character.

That the final colour of the shadows should be black instead of blue, is due, we imagine, merely to the presence of the greater mass of material which, though blue or blue-black in a thin, semi-transparent layer, would become opaque and black in a greater mass.

The final lifting of the film from the glass is the simple result of the repeated hardenings of the gelatine by alum, by the action of the developer, and by the bleaching solution of chloride of mercury, each of which, by causing the film to shrink or contract more or less, tends also to cause it to leave the glass. The action of the final solution of sulphide of potassium is in an opposite direction, inclining rather to soften the gelatine, and this, with the assistance of the osmose set up in the last washing, finally brings about the vermicular swelling culminating on the film leaving the glass.

Such seems to us the explanation of what our correspondent seems inclined to set down to chemical causes, though we can find no possibility of believing that to be the reason, so

frequently has the method succeeded in our own hands. No doubt many of our readers have noticed similar if not identical vagaries on the part of gelatine films that have been over treated with chrome alum, which frequently, besides rendering the gelatine impermeable, brings about the very fault—frilling—it is used to prevent.

PHOTOGRAPHERS AND FIRE INSURANCE.

THE late conflagration at the Paget Dry Plate Works, and the contiguous premises of the Woodburytype Company, together with another fire in Derby, recorded elsewhere, naturally reminds one of photographers' fire risks generally and the high premiums they have to pay for insurance. By the way, we are pleased to learn that both the companies named are fully insured, though they must still be considerable losers by the catastrophe, in the matter of loss of immediate business.

Photographers have always had good ground of complaint at the high premiums they are charged by the insurance companies. In the collodion days photography, by reason of the inflammable materials used, might well be classed as a hazardous business. Furthermore, there is no gainsaying the fact that, at one time, several of the offices had many claims to meet in somewhat rapid succession. But, with one or two exceptions, we do not remember a fire that could be directly attributed to the combustible nature of the materials employed in the business. From the fact, however, that such explosive and inflammable compounds as gun-cotton, ether, and alcohol were being in constant use, coupled with the circumstance that a large number of fires did occur on photographers' premises, the insurance companies were at one time, perhaps, justified in materially increasing their rates. But now that collodion is abolished, or practically so, the risk is certainly reduced to that of any ordinary trade. And, so far as we are aware, of late years there have not been a larger proportion of fires amongst photographic than other businesses. Therefore it is not a matter for surprise that photographers should protest, as they are continually doing, against the high premiums they are at present charged. This is a subject that might well be taken into consideration by the newly-formed photographic section of the London Chamber of Commerce, when it gets to work.

In fixing the rate of premiums, it may be mentioned that the insurance companies have to take into consideration not only the hazard, but the probable value of the salvage in case of accident. Here is an example. A few years ago a photographic friend of ours relinquished business and removed a good portion of the apparatus to his private residence. On insuring it here he had to pay more than double what he was paying on the household furniture, notwithstanding that it was stipulated in the policy that the apparatus was not to be used on the premises. The explanation was this: Salvage furniture was generally of some value, as it might be repairable, but this was seldom the case with photographic apparatus.

It can readily be imagined, when a fire occurs in the studio, that through the medium of the blinds and curtains the whole place is quickly ablaze, and although the heat attained, before it is subdued, may not be sufficient to actually consume the contents, they are generally so much injured as to be next to worthless. For example, the heat may not be such as to injure the lenses by itself, but a stream of cold water projected upon them while warm would split the glasses into fragments. We have seen a valuable portrait lens that was in a studio when on fire which, apparently, had suffered no injury whatever

from the heat itself, but it was cracked into a hundred pieces by the water. Cameras and other photographic apparatus are of little use after a fire, for although they may escape the flames, they may be totally ruined by water.

There are several things in connexion with insurance which are frequently overlooked by photographers. In the policy, for example, it is usually stated that the value of the negatives is limited to a certain sum, usually one shilling each, though some may be worth several pounds. If any higher sum than the shilling be desired, then these negatives must be insured individually. It must not, however, be supposed that the insurance company will necessarily pay even the shilling, unless it be shown that the negatives destroyed were actually worth that sum. Usually the value of any individual lens is limited to ten pounds, unless it is specially referred to in the policy.

Many photographers from time to time add to their stock of apparatus without giving a thought as to whether it is covered by the existing policy. We know that since the demand for large direct portraits there are many lenses in use which have cost enormous sums, for which only, say, ten pounds could be recovered in case of their destruction.

There is another point connected with the wording of the policy which is frequently disregarded by photographers. It is very common in the policy to separate the goods insured into sections, mentioning an amount for each.

In an insurance for, say, eight hundred pounds, it may be worded thus—on furniture, two hundred; on negatives and pictures, two hundred; and on studio and plant, four hundred. Now, at the time the insurance was effected, this sum was ample to cover the property in every department, and with a good margin to spare. But, with an increase of business, the plant has from time to time been added to until its value is far greater than the four hundred pounds. Yet the insurer often rests content, because eight hundred pounds may still be sufficient to cover the value of the entire stock, inasmuch as the furniture, negatives, &c., are not worth the full amount named for them in the policy.

Suppose a fire occurs, and the studio and plant are totally destroyed, while the furniture and negatives suffer but little injury. Although the damage sustained by the studio and plant section might amount to, let us say, fully six hundred pounds, and that by the others jointly to but one hundred—total seven hundred—five hundred pounds only can be recovered, because only four hundred is mentioned in the policy for the plant section. Some insurance offices, however, have, we know, dealt very liberally with insurers under circumstances similar to those just detailed. Insurers should, however, examine their policies occasionally—especially if they are old ones—to see that the amounts are sufficient to cover all losses in case of accident.

An excellent example of the usefulness of photography for scientific illustration is seen in the May number of the *Chemical Society's Journal*, which contains the Presidential address illustrated by a series of reproductions of the diagrams used when delivering it, and which are evidently executed by a mechanical photographic process. For the reproduction of diagrams, of course the objections we hold to the use of engraving processes for the exhibition of photographic results do not apply; but it is satisfactory to see the field that might be legitimately occupied by engraving successfully filled by process work.

In a recent issue of the *Scientific American*, a simple method of making a fluid as a basis for a spectroscopic prism is described, and as

some of our readers who might otherwise wish to experiment in this direction may be deterred from spectroscopic work by fear of the cost of a carefully ground glass prism, we may briefly describe the one we allude to. It consists in effect of a three-sided tin box forming a liquid-tight receptacle, and provided with a neck, closed by a cork, for introducing the liquid. Two of the sides of this box are pierced with circular apertures one inch in diameter, and over the whole of each side so pierced a piece of well-selected, clear, plate glass is cemented. Into this tin case carbon bisulphide is poured and the prism is complete. Certain little precautions, however, have to be taken to enable a success to be secured. Before cementing the glass, the tin vessel should be freed from the slightest trace of grease by washing with a dilute solution of caustic soda or potash, rinsed with distilled water, dried, and blackened inside with a thin solution of glue in ink. To cause the glass to adhere to the bright metal, acetic acid must be used in making the cement. Fine white glue is steeped in water for a while, melted, and the liquid thinned by glacial acid and a drop or two of glycerine added. Care must be taken not to squeeze out any of this cement upon the face of the glass. Forty-eight hours will suffice to harden the cement, and then the bisulphide should be poured in so as to leave a trifling air space when a good cork is pushed in level with the top of the neck. This also should be varnished over with the acetic glue as above. Finally, it is better to cover the prism over with thin, dead, black paper, leaving apertures to correspond with those in the tin.

PHOTOGRAPHY is utilised in the construction of a new balance which has lately been brought before the scientific world. In this novel instrument of precision, after the weight has been roughly approximated, instead of continuing the trials in the usual manner, the beam is allowed to come to rest, which it quickly does by means of an ingenious air buffer, and then the extent of the bending of the beam through the difference of the weights is observed by a microscope fitted with a network of parallel cross wires directed to a small micrometer fixed at the end of the beam. This micrometer is made by a photographic process, and carries figures and lines distant from one-twentieth to one-fiftieth of a millimetre apart. The introduction of Bunge's short-beam balance—comparatively speaking a few years ago—almost revolutionised weighing operations, owing to the despatch with which they could be carried on; it remains to be seen whether the new instrument, in which photography plays a part, will be an epoch marking one.

In the Paris Exhibition is exhibited a collodion product of a remarkable character, neither more nor less than an artificial silk. To manufacture it, pyroxyline was first prepared by the conversion of a specially pure cellulose, obtained from certain parts of young wood, and then dissolved in a mixture of thirty-eight parts of ether and forty-two of alcohol. Through a series of concentric tubes the collodion is forced out, under pressure, in a stream, and then immediately solidifies by contact with water, the thread so produced being wound off on to a bobbin. Next, this thread is denitrated by being soaked in weak nitric acid, which renders it insoluble in ether and alcohol, and also non-explosive. The threads are now dried and used as ordinary silk; they are capable of being dyed, and are about three-quarters the textile strength of ordinary cocoon silk. In appearance it is stated to excel the natural product of the silkworm.

It is not generally known that although celluloid, now so prominently brought before photographers in one of its forms, is not explosive, some samples are, under certain conditions, capable of being exploded. If heated to a certain point, and then subjected to concussion, that kind composed largely of gun-cotton may be exploded by a shock.

A RECENT work by Major Cundill upon explosives may be read with advantage by those who are experimenting with magnesium flash lights, especially those of the pyrotechnic kind. He declares chlorated mixtures to be unsafe, and though his remarks are directed to explosives proper, seeing so much use is now made of gun-cotton in its explosive form, and compounds that, being intended for "instan-

taneous" combustion, must also be ranked as such (they have already caused death), we cannot do better than quote his words of advice.

He writes, "The function of an explosive is to explode. Remember this in dealing with them. If an explosive is described as 'absolutely safe under all circumstances,' do not treat it as some people treat a big dog, and try how much it will stand. There is no explosive within my knowledge which, when exploded in a confined space, does not give off noxious or deleterious gases. . . . In using an explosive with which special instructions are issued, it is wiser to read them before an accident happens than to have to refer to them afterwards to see if they are not issued for some good reason." We conclude our extract by another dry but pregnant remark of Major Cundill's. Speaking of careless handling of these preparations, the result of which is generally a verdict of "accidental death," he says the verdict in such cases would more justly be—suicide or manslaughter.

COLLODIO-GELATINE PLATES.

In your issue of May 10, Mr. G. V. J. Poirin made mention once more of an old favourite process of mine, which he and I were simultaneously experimenting with just four years ago, and which I at one time had hopes might be made for some purposes to supersede gelatine. That hope I am afraid has long since disappeared, not by reason of the failure of the process, but solely on account of the vast change that has taken place in the whole system of photography, and in the requirements of photographers.

It matters not what class of photographers we turn to, we find now that the requirements and mode of working of ten years ago are completely changed. The universal adoption of commercially prepared plates, by both professional and amateur, has not only practically killed the experimentalist, but has established a system based on the principle of not doing a single thing the performance of which can be secured by payment. Consequently, any process or method that requires the exercise of any individual attention beyond development with chemical phases is doomed to neglect.

Still, I cannot help thinking, especially after that little stir the announcement of Dr. Hill Norris's new (?) rapid collodion process caused, that there must even yet remain some few photographers who would find uses for a rapid collodion plate, and who, indeed, would welcome any method by which they would be placed in a position, if not of making the whole of their plates, at least of improving them for special purposes, or in special sizes when required. To enumerate only a few of the possible applications of such a process as the one referred to by Mr. Poirin, and available either for professional and amateur, will not take long, and the list includes making enlargements generally, but especially enlarged negatives, transparencies, lantern and stereoscopic slides, copying and negatives for process work, as well as the production of the humble "tin type." Let us see how it can be done.

As compared with Dr. Norris's marvellous process, the one now proposed is simplicity itself, although it necessitates the making of two separate emulsions—one of collodion, and another of gelatine. I do not think it would be a practical process to work commercially, because the plates must necessarily be more costly than gelatine, and, indeed, could not possibly be made at anything like present prices; while the only advantage gained would be a greater adaptability to certain special purposes than is the case with gelatine plates, but with a reduction in rapidity of working; for my claim in favour of the composite plates does reach to equal rapidity with gelatine, and in that respect I think Mr. Poirin's opinion is the same as mine. I speak, of course, of the highest rapidity possible with gelatine, but they can easily be made as quick as what are known as "slow" gelatine plates.

It would be necessary then for the photographer to make his own emulsions as well as coat his own glass, but as the operations involved can be performed on a bulk of material that will serve for a vast number of films, the trouble and time devoted to each individual plate becomes really very small, and in this respect the process compares very favourably with Dr. Norris's innumerable and almost interminable soakings and washings.

I have said it will be necessary for the photographer to prepare his

own emulsions, though it is true collodion emulsion is procurable commercially, and gelatine emulsion in the dried or condensed condition would also, no doubt, soon become a trade article if the demand arose. But for reasons I shall point out, I think it would be better for the consumer to make his own emulsion.

The collodion emulsions procurable commercially are almost of necessity "washed" emulsions, to insure that they will bear keeping. The operation of washing, though it may not deteriorate the product for ordinary purposes, to my mind certainly does so for this application; and I am of Mr. Poirin's way of thinking that an unwashed emulsion is preferable. Such an emulsion, of ordinary rapidity, and possessing the power of giving any degree of density, will keep for a comparatively long time, though not so long as a washed one, say, probably, several weeks; and as the chief function of the second or gelatine emulsion is to confer the rapidity lacking in the first, the dense slow emulsion is probably the best to use as the basis.

But to gain the highest degree of ultimate sensitiveness both emulsions should be as rapid as possible without sacrificing the density-giving power of the collodion. In effecting this object the unwashed emulsion offers peculiar advantages over the washed, since a preparation with excess of soluble bromide to such an extent as to confer upon it almost unlimited keeping powers may be resensitised with an excess of silver a short time before use, in which state, for a brief period only, it possesses a very high degree of sensitiveness, combined with the most perfect physical properties, and is particularly suited as the basis upon which to apply the second layer of gelatine.

A washed emulsion may be adapted in a similar manner, though not with equal effect, for the reason I have mentioned above. Still, a much quicker, and, moreover, denser result is gained by adding two or three grains to the ounce of cadmium bromide, and, finally, say half an hour or an hour before use, sufficient silver nitrate dissolved in alcohol to leave an excess of about two grains to each ounce, with a grain to the ounce of citric acid. If this acid should make the collodion too "lumpy" or glutinous, substitute nitric acid, and do not "resensitise" more emulsion than can be used up at once, as it rapidly passes into the foggy stage.

In making the emulsion, I do not think any better bromising formula can be adopted than equivalent proportions of the bromides of cadmium and ammonium. Bromide of zinc gives a rich opaque film, not liable to halation, and of good rapidity, but it also has a strong tendency to produce veiled images. The proportions must depend upon the character of film required, but a quantity of the mixed bromides to combine with fourteen grains of silver to each ounce will be ample for anything.

With regard to the second or gelatine emulsion, I need only say that it should be as rapid as can be made without fog, and that it should contain but a moderate proportion of gelatine. As regards the details of manufacture, I prefer a bromo-iodide emulsion containing, say, five per cent. of iodide made by the boiling process, to be made up so that twenty grains of silver nitrate and from ten to twelve grains of gelatine go to each ounce of finished emulsion.

If the collodionised plate be washed in hot water and coated with this gelatine organifier, the surplus poured off rapidly, *but not drained*, and the plate placed in a level position for the thin coat of gelatine to set, the film may then be dried, or, if more convenient, may be exposed wet, and will be found to possess a rapidity at least equal to the "slow" gelatine plates of commerce.

ERNEST GRAHAM.

ECHOES.

THE method of recovering silver bromide from spoilt emulsions or plates mentioned in the leading article a fortnight ago is a most useful as well as convenient one, especially for amateurs, at least so far as the extraction of the silver is concerned. The subsequent precipitation in the form of sulphide follows as a matter of course, and up to this point I think no fault can be found. But I should myself scarcely like to place my trust in a sample of silver nitrate made as recommended in the same article by the direct action of nitric acid on the silver sulphide.

Sulphide of silver is insoluble in dilute nitric acid, but dissolves with tolerable ease in the concentrated acid, especially at a high tem-

perature, sulphur being at the same time liberated. I am afraid to speculate as to what degree of purity is likely to be secured in crystals obtained from a solution in which free sulphur has been digested at a high temperature in strong nitric acid. I should distinctly prefer to fuse the sulphide, or, failing the facilities for carrying out that operation, should send it to the refiners.

I think, however, for amateur purposes, or where it is intended to perform the reconversion into nitrate without outside assistance, the acid method of separating the silver is preferable. Every atom of silver may be thrown down with the greatest ease in this manner, and in such a condition that it can be perfectly freed from all organic impurities and brought to the condition of practically fine bromide or chloride of silver. For reduction to the metallic state there is no better plan—after fusion—than the process with glucose and an alkali. The haloid is boiled with a little caustic alkali and almost any organic substance—such as sugar, starch, gelatine, capable of conversion into glucose or a glucoside—until upon testing a small quantity of the blackened precipitate it is found to be perfectly soluble in dilute nitric acid. After careful washing the result consists of the purest metallic silver it is possible to obtain by any conversion process.

Instead of using acid to separate the silver from the emulsion, caustic alkali may be substituted, in which case the decomposition of the gelatine supplies the necessary glucosides, and separation and reduction proceed simultaneously. But it is extremely difficult to free the fine deposit of metallic silver thus obtained from the filthy black or dark-brown liquid accompanying it. I have known traces of this discoloured liquid to remain after many days' washing, hence I prefer to get rid of the gelatine first of all by the separate treatment with acid.

In Mr. W. M. Ashman's interesting paper on emulsion processes in photography, I notice he fixes the date of the first mention of an emulsion process—on the authority of Dr. Eder—as far back as 1853, Alexis Gaudin being the experimentalist whose work is referred to. I cannot lay my hand at the present moment upon my reference, but I do not think this is the earliest suggestion of an emulsion. In one of a series of works published by Bingham—if I mistake not, in the "forties"—reference is made to an emulsion, or what is now so called, of iodide of silver to be spread upon glass plates or paper. As this was anterior to the introduction of collodion—1840 was, I think, the date of the work—the vehicle mentioned is gelatine, and that, I fancy, will rank as the earliest instance of a gelatine emulsion.

By the way, it seems curious that Mr. Ashman should adopt the collodio-chloride emulsion as his type, since it was neither the earliest nor the best known. On the contrary, chloride of silver was the last of the haloids applied to emulsions, and has, perhaps, been least used of any.

After reading the fearful description of the new instrument named the actinograph, I cannot help congratulating myself that I had had opportunities at an earlier date of judging for myself of the difficulties and troubles of landscape photography. Had it been otherwise, and I were now contemplating embarking in the fascinating and fashionable pursuit, I am quite certain the perusal of the terribly "scientific" instrument would have changed my intention. As it is, I am content to go on exercising my own judgment in the matter of exposure, feeling certain that I can thus secure at least as high an average of accuracy with far less trouble.

The inventors of the terrible instrument, however, seem to set up difficulties on purpose for it to cope with. Practically, they say there is no such thing, or very little, as control in development. That "the effect of abnormal addition of alkali is merely to hasten development and eventually to fog the plate, and the effect of abnormal additions of bromide is simply to retard development and eventually to prevent it altogether." Now, if that be not "control," I don't know what it is! But it requires to be applied with brains, instead of *actinograph*!

What horrible sufferings the users of German dry plates must have to undergo! From the interesting "Foreign Notes" column I gather that the latest trouble is a form of plate with "black rims," black edges, in fact, which fit it better for mourning purposes than for the ordinary pictorial application of the photographer. Herr Stoll attributes the defect partly to the employment of "soda as a finer," and partly to the paper used in packing, in which latter opinion Herr Vogel agrees. I don't know what "using soda as a finer" means, so

can't make any suggestion; but as regards the paper, I would propose the use of a *finer* sample, containing less acid sulphurous or otherwise. Dr. Vogel's view does not reflect much credit on the quality of German paper, nor on the judgment of German plate packers.

The same speaker then gave his experience with a new developer, which is called "paraphenyl diamine," and with which "clouding" is easily produced. What in English are "paraphenyl diamine" and "clouding?" Another funny substance mentioned in the "Foreign Notes" is "brenzcatechine." I know what *catechine* is, but what means the prefix?

It is refreshing to find that there still exist some of the old style of enthusiastic amateur, for he must be an amateur who, according to the report of the Pacific Coast Photographic Association, in order to help to complete a series of lantern slides to illustrate a district, has undertaken a journey of 800 miles in order to secure a single picture. The man who would travel all the way from London to Aberdeen on a similar errand would be considered "plucky" in this country, but he would undertake a light task, and one that might be performed in luxury, compared with that of the gentleman whose duty it is to penetrate the wilds of California, mostly, no doubt, on foot or on horseback in order to secure a photograph of the San Diego mission. Bravo!

In "Answers to Correspondents," Mr. W. A. Meigh mentions an effect of backing plates which, at the present day at least, is almost, if not entirely, overlooked, namely, the increased clearness and density of the negative obtained. The prevention of that form of halation caused by reflection from the inner back surface of the glass is usually supposed to be the only function of the backing, but it does not require a great deal of consideration to show that the principle of its action in that capacity may be extended; it is only where strong contrasts exist that the effect of halation as such is distinctly visible, but it is clear that the same sort of reflection in a less degree is going on over the whole surface of the plate. This subsidiary reflection, while not sufficiently powerful to form a double or blurred image, suffices to produce an action on the film, which is equivalent to a brief exposure to diffused light, and which produces a result precisely similar to that of the "auxiliary exposure" on a so fashionable. In other words, by producing a slight amount of general veil it gives an effect of increased exposure, but this at the expense, of course, of absolutely clear shadows.

It is not necessary to suppose that absolutely clear glass is either necessary or desirable in a perfect negative, but it would not be difficult to show that any departure from such absolute clearness produced by the effect of diffused or reflected light inside the camera is a decided objection. The action of a good backing in thus preventing this slight general veil is very easily proved by covering only a portion of a plate with the backing material and exposing on an ordinary subject in which there is no tendency to halation proper. The result will undoubtedly be a clearer image on the "backed" portion of the plate, and most probably an apparent *retarding* action, or, at least, an effect of decreased exposure. For landscapes, including distance, for cloud negatives, and for all subjects in which delicate gradations exist, which are liable to be lost, the practice of backing is of the utmost value, the resulting negatives possessing a far greater printing value and better gradation, without any increase of density or of the time required in printing. To such negatives, in fact, the distinction between "intensity" and "density" specially applies—they are more "intense" without being any denser.

Mr. A. Cowan's way out of the difficulty of conversion of French weights and measures into English is beautiful in its simplicity, and it is surprising that it should have to be explained to any adult individual. But there seems to be a tendency on the part of many when the idea of a "gramme" or a "cubic centimetre" enters the head to allow all common sense to take its departure. One such individual amused me a few years back, and showed me to what depths of helplessness an otherwise pretty smart fellow could descend on some points. Quarrelling with a formula which was stated in terms of the metric system, he wailed out something to the effect that if only the "lunatics" would state their formulæ in "parts" it would be plain enough. I ran my pencil through the "grammes" and substituted "parts," but it was some time before I could persuade him that the formula was not thereby altered, and a still longer time before he would freely acknowledge he had been a—"duffer."

Our societies are indebted to Mr. Warnerke for a very practical suggestion. In the annual selection of officers, especially members of the Council, the general members like to have some guide as to the utility of their selections, and to guard against merely "ornamental" names being added to their lists. The Parent Society some years ago started the rather cruel plan of publishing in the JOURNAL just before "nomination day" a list of the attendances at Council meetings during the past year, in which it was always noticeable that the President with his "good boys" headed the list, while those whom the powers that then were wished to dispense with were correspondingly low down. It used to look rather "rough" on "Mr. A." to find that he had only a little "2" to place alongside the President's big, big "9;" worse still for Mr. B. with his "1;" but Mr. C.'s chance of re-election was utterly hopeless after the appearance against his name of the fatal "—." I never could understand quite why that system fell into disuse, but I have a strong suspicion that the "good boys" got into irregular habits, while the newly-elect "Phyllistines" became the most constant attendants. Could it be but fancy, I wonder?

Now Mr. Warnerke suggests that a flash-light group be taken of each Council meeting, and the idea is not a bad one, for the publication of a sheet of pictorial records would supply all the information required by those interested, without unnecessarily gibbeting any particularly "irregular" member. There is only one difficulty I can see, namely, that where the friendly pipe or more aristocratic cigar accompanies business, the excluded smoke may interfere with definition; or, worse still, the presentation of the revered features of the President adorned with a short "cutty" might so influence the minds of the electors as to destroy all confidence in him. I don't know whether the "smoking habit" prevails at Pall Mall Councils, but I sat next to a councilman who had just come up stairs one night, and if it was his "off side" neighbour that smelt so strongly of tobacco, I am glad that I was as far off as I was.

The mention of Sir Jocelyn Coghill's name in the report of a recent society meeting takes back my memory to the good old days when, if there were fewer photographers, there was proportionably more good work. In those happy days, when to be a successful amateur photographer, especially a successful exhibitor, meant something more than the possession of the wherewithal to purchase a camera and a dozen plates, when it was, in fact, necessary to know what you were doing, and to know it well, and, what is more, to be able to do it yourself—in those days Sir Jocelyn's name was one "to be conjured with" amongst photographers of the first rank. Would there were more of them now and fewer "pot hunters!" JUNIUS.

A DEFENCE OF THE STEREOSCOPE.

It seems to me incredible that the attempt (and to my mind a laudable one) to revive the popular interest in stereoscopy should have met with opposition in a quarter least to be expected, viz., from a contemporary journal of yours that possesses a title which should cover all branches of the art of "light writing," and therefore should be not only interested in, but encourage all possible useful, artistic, or commercial developments of it. Mr. Chadwick is quite able to make good his case by showing in what way the nearest approach to perfection can be obtained as regards the preparation of stereograms, but if no one else takes up the cudgels it may be thought there is no real revival or *bona fide* interest left in an instrument entitled to rank as one of the best for scientific amusement. It certainly has not the same practical value as the microscope and telescope has in some hands, but from my experience during the past twenty-five years, in which I have been brought in daily contact with purchasers of scientific instruments, I can truly say that the majority of persons who buy these and kindred instruments do so mostly for amusement, or as a hobby, for the pleasure derived from their use is to them as great as a game at billiards or lawn tennis is to others, or may be to themselves at another time.

After work must come amusement or recreation in some form, and if by stereoscopic photography pleasure can be derived by the operator and amusement afforded him and a circle of friends afterwards, there must be some use in it, and it is, therefore, a peculiar objection to make that a stereoscopic slide is *not* an art production and has no "atmosphere" in it. Why one picture of the stereoscopic slide is acceptable, and the two together viewed through a stereoscope are not,

I fail to see by any process of reasoning; and as regards objection to solidity one might as well say have no sculptures, as a painting shows the subject so much better. There are few but admire nature, and the nearer any representation approaches the natural, not only the more effective is it, but the greater is the pleasure derived from viewing it. I call to mind reading the other day about two friends, one a sculptor and the other an artist, having an argument as to which was the more perfect art of the two, the sculptor claiming his was, because it was possible not only to show the form from one side, but to give a faithful representation (in a statue) on all sides, whereas the artist rejoined that if a bet was made he could also show all sides of a figure on one canvas, with the addition of correct colours. By an artistic trick he was able to win the wager, by showing not only the figure as seen direct, but reflections in mirrors placed round the room of the other points of view of the same figure. The artist's license is largely availed of in order that distance, solidity, and space shall at once appeal to the senses, the contrast of colour being the chief means to that end; but with photography no colours can be relied on, and therefore, if by employing the two eyes the Creator has given us we can see with *solid* effect, why not do so; and the energies and knowledge we possess should be used to obliterate faults and bring about the nearest approach to perfection, and the stereoscope should not be allowed to lie dormant because by a wave of fickle fashion it has been temporarily shelved.

The object of the stereoscope being to combine two slightly different pictures so as to produce to the mind the same impression as would result from the view of the object *naturally*, were it actually before us, it is only necessary to take care the instrument is sufficiently carefully made to insure proper vision, and the stereograms are taken from points of view equivalent to the average distance between the eyes, and, when printed, mounted correctly. As regards the instrument, there is no doubt it should have the means of quickly and exactly adjusting the distance between the two achromatic lenses, and for this purpose, where a person is odd-sighted or astigmatic, the eccentric action patented by Mr. Douglas Hamilton may be found very useful, for it not only separates the lenses the necessary interval to allow of persons whose eye centres are from two and a quarter to two and three-quarters getting their proper width, but allows of the plane of the two to be varied to correct any error of axial refraction. If each lens has a separate focussing adjustment, then the eyes can be accommodated to correct focus without having recourse to spectacles.

I feel sure, from a commercial point of view, the stereoscope can be again made a popular instrument if well constructed at a moderate price, for amateurs will be able to make their own slides with equal ease as they now do lantern transparencies; and with an increased demand professional photographers would find it worth while to produce glass stereograms at prices as low, if not lower, than the celebrated French slides. Why should not some of the semi-transparent mediums be tried as a substitute for glass? They would probably be found equally suitable for producing the beautiful transparency necessary for the pictures, and would be lighter and not so likely to get damaged. I trust the revival of the stereoscope in popular favour will be thorough, and it will again take the position it deserves as a scientific instrument.

G. R. BAKER.

ORTHOCHROMATIC PLATES IN COPYING OIL PAINTINGS.—III.

PERHAPS there is hardly any other part in the operation of copying oil paintings which gives more trouble, when operating in places not specially suitable for the work, than the difficulty of overcoming reflections from the surface of the canvas. It does not fall to the lot of every novice to have a studio specially so constructed as to enable him to overcome this trouble with ease; for doubtless it is the case with most amateurs, and very often with professionals also, that they are called upon to undertake such work in places where several cross lights exist, and also where the surroundings are such as to cause no end of reflections. Neither is it practicable on all occasions to get the painting sent to the studio, and, therefore, an operator must just battle as well as he can with the circumstances as they arise.

A by no means uncommon case is where an operator is called upon to copy some paintings, say, in an artist's studio. In such a case the work is not so difficult to overcome, for it is more than likely that such premises will be found to have a sloping top-light. Still, there will be found on placing the picture on its support that this difficulty is nearly always more or less present. A little attention, however, to the surroundings of the room, and by carefully placing the picture in the best light available, will in the end amply reward what little trouble is expended. In such a case, first let the operator place the picture (which should be taken out of the frame) under the best light

the place will afford; this done, let him scrutinise carefully and see what reflections are present, and having found out these, his next step must be to find out the cause. This may arise from several sources, such as a glazed picture hung on the wall, a white piece of cardboard lying about, or any other article that is reflected from the face of the picture, which acts in a sense just as a mirror. A little "flitting" of such prominent objects will in due time tend to remove the difficulty. Attention must also be given to the floor and the articles on it; and where such are objectionable they should be covered up with some material, such as dull cloth or drapery; and, finally, let the operator cover up all the brass work and shining parts of his camera, and even go so far as to button over his waistcoat and shirt front and collar, for I have seen these cause the trouble. An artist's studio is by no means a place to be despised for working in at this branch of photography, and with proper and due precautions taken to overcome reflections, most excellent results are to be obtained.

One word about the tripod. My advice is, don't go about this class of work with an ordinary three-legged affair, but get a good studio stand, and one that will enable the operator to square his camera to the picture without much trouble. It is not at first an easy matter for a beginner to get the picture and camera so set as to register in correct shape on the ground glass. A very little deviation from the true position of the camera to the picture will suffice to make one side or top or bottom of larger or smaller proportions; hence, particular means must be employed to insure a correct registration. In specially adapted studios, where there are provided means for overcoming this difficulty, but little trouble will be met with, but an amateur working on and off will experience some difficulty in this respect also; but perseverance, however, with simple means, such as carefully measured tape lines, and also by a system of lines ruled on the ground glass of his camera, will generally overcome this difficulty.

An artist's studio is at all times to be preferred to an ordinary room for this work.

Let us now proceed to view the subject, however, from the standpoint of having to work in an ordinary room. Here, most likely, we are driven to contend with one or more windows, which, of course, means a side light, and where there is more than one window in the room I have no hesitation in saying the first thing to do is to select the best one and proceed at once to block out entirely all the light from the others. Do this in such a manner as to have "no light behind the camera." Then proceed very much as in the previous case and examine for reflections. Find out their cause; which done, remove them. The picture must be placed so as to receive as even an illumination as possible.

It will sometimes be found, in the case of pictures which are what some may term coarsely painted, that is, where to secure some desired effect the painter has had recourse to apply the paint in masses, that such will show little knobs or protuberances, and these little points, standing out as it were from the surface of the canvas, are very prone to cause bright specks of light, no matter how carefully the picture may be situated as to lighting. If such should give any bother, and if after all possible means have been employed to overcome them in the lighting, then an operator should not hesitate just to go ahead and make his exposures, with the view of bringing out a negative as full of detail as possible, notwithstanding the presence of these objectionable little specks of light. In my experience I, however, never failed to get rid of them subsequently, not by the application of a retoucher's knife or any system of rubbing down, but by what I consider a far more preferable method—of throwing off a transparency, and then with an ordinary system of retouching remove these defects. In fact, I sometimes think that there is no negative, however successful it may be as a direct outcome from development, but is capable of being improved upon by throwing off a transparency, and then from it print a duplicate and final negative.

Once an operator grasps the situation and comes to realise the improvements and benefits which can be got from such, he will not think of the extra bother and cost such an operation entails.

To some it may appear a roundabout way of going to work, but I can safely say that flaws and defects in an original negative are sometimes easily removed, even in cases where a novice would deem it impossible to remove them by merely looking at the first negative.

Of course such a procedure necessitates some slight acquaintance with retouching, and I think every one who aspires to the name of photographer ought to possess some knowledge of this most necessary adjunct to the art.

The above remarks refer more particularly to small defects. Broad masses of reflected light should never be allowed; when such are present then the lighting is wrong, and an operator ought to move things up and down till such are overcome.

It is wonderful what an improvement, however, is effected by

working up a transparency by contact, and then pulling off a duplicate and improved final negative.

And now just a few remarks as to the development of orthochromatic plates. I am aware it is at all times good advice to use the formulae recommended by the makers, but in this case I make bold to assert I have got better results on Edwards's plates by a judicious use of the following. When going to develop, prepare one ounce sulphite soda; twenty ounces water.

Saturated solution carbonate soda.

Saturated solution carbonate potash.

A ten per cent. solution bromide potassium.

When going to develop, exercise judgment as to the quantity of solution necessary to well flood the plate. Of course, much depends here on the size of the dish and plate which you work in. I prefer always to work in a large white porcelain dish. I can see when such a dish is clean and when it is dirty better than would be the case in a black one. I like the dish large, because it is not so "sloppy" to work in, and hence the developer does not go over the edges. Another advantage which a big dish gives is this: It permits of a good dose of developer being used. Some may say, What does it matter whether I develop, say, a whole-plate with one and a half ounce of solution or three ounces of same, provided the solution be of the same strength? Kind reader, there is a difference; and if you want good harmonious negatives, let me impress on you the necessity of using a full and liberal supply of developing solution. Just try the experiment.

Well, having made up your mind as to the score of quantity, take, say, two grains of pyro per ounce of the sulphite solution, and add same "dry" to it in a wide-mouthed tumbler, and don't forget, having given a liberal exposure, to add a little bromide (only a little).

Now flood the plate with this, and while on the plate add cautiously equal quantities of the saturated solutions of carbonate of soda and potash, about ten drops of each at a time, until development is seen to begin. *Don't hurry!* If your exposures are anywhere near right, and you have not put in too much pyro, you need not fear chalky negatives.

I don't say this formula is new, but I do say it is a jolly good one.

Wash well before fixing, and don't forget to run the plate through a weak solution of chrome alum before and after fixing.

Common alum is not in it with chrome alum.

The secret of success lies in slow development, a liberal quantity of developing solution, and pyro dry added at the time of flooding the plate.

With Edwards's isochromatic plates density is easily got, so too much pyro should be avoided at the start, and if during development it is seen more vigour is wanted, it is easy to mix up a fresh developer with more pyro and bromide.

In my hands most excellent results are obtained in the copying of paintings, working on the lines I have laid down; and I am sure that were many amateurs to turn their attention to such they would find pleasurable enjoyment therefrom. T. N. ARMSTRONG.

"GOOD BUSINESS."

Now that everybody who has to work for a living, including photographers, is complaining of bad business, it is time to think over some method or methods of reviving the same. When trade is depressed, it has often been found that the introduction of a novelty will cause a run, more or less sustained, according to the hold it obtains on the public, and the extent to which it hits their purses. The difficulty with photographers just now is to find a novelty, but there is a chance that the re-introduction of what was a novelty some time ago, and has since been forgotten and overlooked, might be just as useful. The nearest approach to novelties that we have at present are flash-light portraits and permanent portraits printed in platinum and mounted on india-tinted plate paper in imitation of steel engravings. I remember some ten years ago, when operating in the little island of Malta, we had quite a run upon what was then a genuine novelty there, and which I have never seen introduced here. We gave it the title of the "new group of one," and it was so in reality, being a portrait of one person in two positions in one picture.

It must not be imagined that I refer to the so-called duplex or triplex portraits, for the "group of one" differs very materially therefrom, in being to all intents and purposes one picture, three-quarter or full length, whereas they were really two or three medallion or cameo pictures, printed on one piece of paper and mounted on one card.

The method of taking the "group of one," which I fancy may be a very successful introduction into most studios, is very simple, and all

the apparatus required in addition to that in use in all studios can be procured very cheaply. Two wooden doors will be required to be fixed in the camera. These must be of a similar form to the so-called folding doors often found between two rooms, and so constructed that each of them, when closed, occupies exactly half of the camera, and fit perfectly together, the inside edges being perfectly plain and accurately planed. When the doors are made they should be hinged on to the camera so as to open inwards, and as close to the focussing screen as they can possibly be placed. Of course, it is needless to say they should be dead blacked. To take the "group of one," open the right hand door only, pose your sitter carefully as though there were another figure there, and focus on the part of the screen which is illuminated, put in your dark slide, and expose; then close the right hand door and open the left, *without moving the camera*, and re-pose your sitter on the space of the focussing glass now illuminated, which will necessarily be the opposite half to that exposed before. The sitter may be in the same costume, or different if desired, and capital results may be obtained in such poses as standing up reading a paper, or sitting down listening to the same, in fighting attitudes, &c.

On developing the plate there will be no mark to show that there have been two exposures, the whole appearing to be one picture, that is, of course, if the wooden doors have been accurately made and the camera has not been shifted between the two exposures. It is in no wise a necessity to show the sitter how the thing is done, these pictures usually being thought to be the result of careful combination printing. When giving the order for a pair of these doors, impress on the cabinet maker that the edges must be plain and not have a rabbet or ledge, which would give a line down the centre of the picture.

Ghost pictures have, I think, had their day, but if any one should like to introduce them in any town where they have hitherto been unknown, perhaps the easiest mode of producing them is as follows:—Pose and focus your sitter, carefully noting the exact position occupied upon the focussing screen, and when the picture is exposed be careful that no articles of furniture in the picture are moved, or if they are, remove them altogether from the space occupied by the picture. Now, after your sitter has departed, introduce a draped figure into the space formerly occupied by the sitter, stop the lens down, and give an instantaneous exposure; on development the result will be found to quite equal the spirit pictures taken by any of the more intricate and difficult methods. In some places this may be found "good business," but I would advise the photographer who introduces "spirit pictures" to especially state to his clients that they are *trick* pictures, or he may lay himself open to a charge of obtaining money by false pretences.

The "Angelo," or "statuesque," portrait is obtained by placing a cardboard pedestal in front of the sitter, whose hair and face are powdered, and shoulders draped with white, and using black velvet for a background. These pictures are sometimes very effective, resembling a photograph from a marble bust; and though they have been to the front for some time in America, and on the Continent, they do not seem to have been introduced by many photographers in this country, and may prove "good business" for some one yet.

In the States, caricature portraits find considerable favour, and are produced in much the same manner as the "statuesque," without the necessity for powdering or making up at all. The main advantage of this style of picture lies in the fact that it is the figure only that is caricatured, the face being photographed from the living model, and the figure being from a picture placed in front of the real figure. These foreground pictures may be drawn in crayon by any one with a knowledge of drawing and a natural taste for the grotesque. As the picture is avowedly a caricature, there is no necessity to make the drawing the size of nature; in fact, if the body is drawn about two feet or two feet and a half it rather enhances the effect. To those who are unable to manufacture their own foreground drawings, I would add that they can be obtained in considerable variety at a very low figure from Mr. C. M. Coolidge, of New York. I am not aware that any of the London dealers have as yet stocked them, though once they are asked after I have no doubt they will be able to supply them, and by so doing I have no doubt they will insure "good business" to many of their customers. In introducing novelties in the photographic business, I would beseech one and all to introduce no more new sizes; what with midgets, promenade midgets, *cartes*, Malverns, cabinets, promenades, boudoirs, small panels, large panels, Imperials, &c., I opine we have variety enough and to spare so far as size and shape are concerned, although I cannot say I believe in any set size or shape for landscape or general outdoor work, which pictures should always be cut to suit the subject, and not by any rule but that of art.

C. BRANGWIN BARNES.

THE DEVELOPMENT OF THE DETECTIVE CAMERA.

The primary principle of the detective camera is its portability. Its original *raison d'être* was its freedom from the tripod. An operative camera without a tripod was, of course, impossible in the time of slow plates. A portable camera did, indeed, anticipate the quick plates, for Mr. Brainerd, at least, visited the Centennial Exposition in 1876 with a small legless camera, with which he managed to break the rules by taking pictures here and there without a permit; but this portable camera required a rest and time exposure. With the advent of the quick plate the emancipation was complete. This emancipation was not accomplished without sceptical opposition. Mr. Schmid, of Brooklyn, who first patented a detective camera, was confidently assured that the idea was infeasible. There must at least, he was told, be a rod or upright of some kind upon which the box might be rested while focussing was being accomplished. When Captain Ericsson proposed to propel *veasela* with a screw in the stern, the experts asked how under heaven he expected to steer the craft. A boat propelled from the stern could not, they said, be steered from the stern. The experts were, of course, mistaken. So were the photographic experts who cavilled about the focus. The focus is merely a matter of arithmetic; and just as the quick plate and automatic shutter banished the tripod, the lever and indicator removed the necessity for ground glass and cloth. These two primary principles being settled, there came a less vital but highly important element in the "finder"—a camera-obscure attachment which revealed to the operator the scope of the lens. This finder bears precisely the same relation to the camera that the sight bears to the rifle. "It is not used in rapid skirmishing. No operator could be considered fully skilled who was dependent upon the finder in rapid or stealthy work. An operator dependent upon his finder would be continually at a disadvantage. But while it is not invariably brought into play, the finder is a necessary adjunct, and we should as soon think of leaving it off the camera as we should think of leaving the sight off the rifle."

Upon the basis of these three elements—the shutter, the focussing lever, and the finder—the modern detective camera has grown. Step by step it has developed from a crude and primitive beginning to a mature, exact, and more or less perfect instrument. In many respects this growth has been remarkably slow—slow for an invention of American origin. Perhaps this was because for a long time the portable camera was looked upon as a pretty toy, scarcely entitled to scientific attention. The immense significance and utility of the camera were long overlooked, under the supposition that serious and particularly artistic work could be done with the tripod camera only. Since it was decided that the detective had come to stay, some interesting scientific developments have been made in its construction. Some of the latest types are really worthy of admiration. But there is still much to be done.

It has always struck me as curious in the matter of photographic apparatus that so many good ideas should be wretchedly executed, and that so much good workmanship should be lavished upon mechanism that is unreasonably awkward. I have never heard this phenomenon satisfactorily explained.

In its best forms the detective of to-day is a beautiful machine, capable of doing work of a high degree of perfection, and imposing upon the operator the minimum of inconvenience. As compared with the tripod camera, the portable camera, in its better forms, has absolutely no limitation but that of size, and this is neither an artistic nor a scientific limitation. It is a limitation in the size of the immediate print, but enlargement somewhat modifies this deficiency. Certainly there are portable cameras so small as to seriously impair their usefulness. The quarter-plate, $3\frac{1}{4} \times 4\frac{1}{4}$, should, I think, be the minimum of size. The 4×5 plate seems to me to be the ideal size, small enough to be portable, and large enough to be practical. A 4×5 plate allows for some reduction in making lantern slides, and this is desirable even with perfectly sharp negatives. Slides made by contact are relatively deficient in crispness and brilliancy. Contact slides shown in the group are often very satisfactory, but when shown with slides made by reduction the strain is severe.

All perfect portable cameras are arranged for time exposure, which removes any limitation imposed by the speed of exposure. It has been very illogically urged that a camera made for "detective" work should be built for that work only. It is true that the primary significance of the instrument should not be forgotten, but it cannot be improper to fit a camera for all the work it can possibly do. There are a number of highly important reasons why the detective should be capable of use in time work at short notice. When taken on a journey a camera should be ready for any emergency. The detective should, indeed, be the universal camera in the matter of equipment. And this does not necessarily imply any deficiency in the arrangement of its strictly portable apparatus.

In other words, the portable camera begins where the older camera leaves off. It begins with all the capabilities of the tripod camera, and adds to this capacity many functions of which the older camera is incapable. It is the camera of the future. It has led the way in many of those directions in which the tripod camera is bound to follow. The idea of the finder and of the focussing lever or screw has already appeared in the conventional apparatus. The detective is the pioneer. It has made us impatient with all except the most convenient forms of camera, whether worked with or without the tripod.

Yet the best of portable cameras is still far from perfect. The ideal detective camera will be a greater triumph of mechanism than any we have yet seen. It will have a certain number of features which we may conjecturally enumerate. Some of these features have already been realised, in fact. It will have two or more lenses—long and short focus—within the box, and quickly interchangeable. It will have a quickly operative focussing adjustment for both lenses, and a simple system of stops quickly changed from the outside of the box. It will have a shutter with great versatility of speed, and a changeable aperture for different conditions of exposure, operated between the discs of the lens or behind both, with a spring that will never vary in strength. It will have a substitute for glass plates in holders, yet better than the modern paper or film. It will carry sensitive surfaces for at least a dozen negatives, and the more the merrier. It will change the position of these sensitive surfaces without opening the box at any point to the light. The camera of the future will at least have these features, and all these operations will be effected from the outside of the box by mechanism not discernible to the passing glance. The camera itself will be inconspicuous in form, of light weight, and moderate price.

ALEXANDER BLACK.

—Anthony's Photographic Bulletin.

JACK AND I IN NORWAY.

I.—NEWCASTLE TO BERGEN.

"Yes, Norway is the place for a month's good photography when you have a month to spare," exclaimed Jack, when I met him at the Glasgow Convention, where he turned up immediately on his return, having hurried up the latter part of his trip to get back in time for the week's Convention outing. "And look here," he continued, "if you care to go next year, I'm your man. You just bear it in mind; and we'll go over together, say next June."

"All right," I said; "if nothing comes in the way I am open for the trip."

So the matter was arranged; and from the time of this conversation up to the date on which to go the proposed trip Jack posted me up in all the various items necessary to take to form a complete kit. As the roads were rough and the space for luggage limited, owing to the very primitive mode of travelling over them, Jack got me to build a travelling case to hold all the photographic apparatus by itself. Our size was whole-plate, and, to save the carrying of glass, we arranged to work with a roller slide and films. The camera, with lenses, shutters, focussing glass, finder, &c., were packed into a canvas waterproof case—size, 11 x 12 x 6 inches—fitted with a broad shoulder strap for carrying. The roller slide, with black velvet focussing cloth rolled round it, was fitted into a similar case—size, 12 x 9 x 4 inches. These two cases were arranged to fit into the special packing box along with other things, such as the tripod stand, reserve stock of rolls of films, canary cloth and ruby paper, dark-room lamp, a hammer, screwdriver, nails, tacks, string, candles, with every necessary added that was likely to be wanted; and they all came into requisition pretty much, I can tell you, before we were done with our journey.

The box for holding all was thirty-six inches long, sixteen inches deep, and six inches across; it was fitted with a loop and padlock, but this was a mistake, for the unavoidable rough usage during travelling caused it to get so crushed and broken that it had to be repaired over and over again. I would recommend a lock set into the box with the holder set into the lid as a safer and handier arrangement. We had a strap screwed to each side and buckling over the top, which was a great convenience when handling. This box proved on the journey an invaluable packing and carrying receptacle. It was just a right size—rather too neat a fit sometimes—to fit on to the back of the conveyances used all over the country, and named carriages and stole-carries (the spelling is doubtful, but they are pronounced so). We found that the box would not have done to be any larger, for in some cases it took up the space from wheel to wheel, just filling without grazing, and when we stood it on end we found it too deep to fit under the seats of some of the vehicles. The length of our box—thirty-six inches—was determined by the length of the tripod stand, so that if a shorter tripod was used the case could be made so much shorter to fit; and where the apparatus is smaller the other proportions would be comparatively less. One thing to be observed is this, for convenience' sake, keep rather within our sizes than over them. The carriage has but one seat and carries but one traveller, the stole-carry is seated for two. The body of the vehicle behind the seat is where the luggage is packed, and on the luggage the driver or caretaker sits, for, as a rule, you drive yourself, so that on the way, when any picturesque bit strikes the fancy, you just pull up, off with the box on to the road, out with the apparatus, take your picture, pack, and away again, not taking more than ten minutes to do the whole thing. Jack had been there before, and he knew exactly what was wanted. Another thing that he was most particular about was the carrying of hammer, tacks, string, &c., all of which we found absolutely necessary during our journey.

I thought that Jack was overdoing it when he told me that none of these things were to be obtained when travelling in the country districts—and it was pretty well all country districts. He said that if I asked for a piece of string they would very likely hand me the dried twig of a tree—and trying it during the journey that was really offered me. We arranged to go from Newcastle to Bergen in the *Norge* in preference to going by the

tour steamers that take you about from place to place. We chose the *Norge* because, when we reached Bergen, we were free to go where we pleased, and stay as long as we liked at suitable places and pleasant spots without being bound by time and circumstance, as one unavoidably is when touring through the country in a floating house. Some may prefer the water-touring system, but, as a matter of choice, commend me to the other, for by it we enjoyed freedom and pleasure beyond our most sanguine expectations, and any who follow in like way will find it full of charming enjoyment.

We reached Newcastle on Tuesday, June 5, and at six o'clock in the evening we started in an old river tug away to the *Norge*, which was moored a few miles down the river. I had not been on the Tyne at Newcastle for years, but the same old feelings that had possessed me when it was a more familiar scene again came surging up. No matter where you look, all along this river near to the town, one is impressed with a still feeling of general desolation hanging all around: dilapidated stores, broken walls, chemical works out of repair, stony patches, showing here and there at the river's edge, deserted-looking villages, everything looking dirty, dark, and grimy, with but a healthy-looking house and patch of green left here and there to brighten up the pervading gloom. We sail on, leaving behind us the depressing influence, and our spirits rise as we come along side the *Norge*, for, white from stem to stern, she looks like a great white swan lying in the rippling water waiting for us, and panting impatiently to get away.

We were lucky enough to be among the early visitors of the season, so that there was plenty of room on board the boat: we had some sixteen passengers in all. Jack and I got a sleeping cabin to ourselves, and it was very comfortable indeed. In our company there were three clergymen, but there was not a Jonah amongst them, for the Captain informed us that the sea on this occasion was not really as rough as usual. We had on board a lady and gentleman who were going to travel Norway on tricycles; they also carried apparatus to photograph on the journey. It seemed to me that in such a hilly country they had some hard work before them. Mr. Gade, the American Consul at Bergen, was with us. He has an estate, called Fantoft, a few miles out from Bergen, on which is built one of the old Stavkirke, or wooden churches. He kindly invited us out to see this curiosity. It had been removed from Fortn, on the Lysper Fjord, and erected at his place.

We no sooner got free from the breakwaters, and out into the open sea, than the vessel began to tumble about a bit. Not being a good sailor at the best of times this made me uneasy. I did not get exactly sick, but squeamish, you know; I believe one half of that sort of thing is produced by thinking about it. Jack never gets sick, and, hence, never has sympathy; but he is great on medicines, and he insisted on me trying ten drops of his *cuscuta-agrafa*, which I did. This special specific was good for everything, and Jack had it in a newly-invented dropping bottle, the mechanism of which he was explaining to me during the time he was dosing me, then he put it away carefully into his hand bag; but, alas! when he went to his bag again the bottle was empty—it had dropped all away into his tobacco; the patent had gone wrong somehow, and Jack was left with nothing but a medicated smoke for the rest of the journey!

As we neared Bergen the custom officers came on board, but they passed the photographic case without any trouble. I fancy that they must be getting familiar with "sets" of every size and description now.

In the sunshine of the morning we sailed into the Bay or Harbour of Bergen. The first view we got of the town was strikingly picturesque, shut in all round by mountains, the white houses, red-topped, rising tier on tier from the water's edge and clustering away up the hill sides, produced a charming effect. To the left on entering the bay, and filling up the immediate foreground, were some rather imposing buildings standing out in strong relief and looking like forts or military stations, all the more effective when compared with the white wooden houses settled in hundreds on the shelving rocks, quite filling up the background. The centre of the view was filled up with streets of more substantial buildings—banks, warehouses, churches, &c.—whilst away to the right the commercial part of the town is situated, where nestling close down to the water's edge the gable ends of stores and warehouses were hanging in a dangerous-looking position over the bay, not one in twenty of them standing plumb. These house-ends lying over the water were painted every conceivable colour, which the sun caught up, reflecting them in the bay, lending a holiday aspect to the scene, enhanced by the dozens of rowing boats dotting the dancing waters all over; whilst in the near distance the hundreds of masts of trading vessels standing up dressed in their slanting network of ropes and ladders gave a finishing touch to the picture, that looked a perfect model of a pretty seaport town. As we neared the landing stage, we took a very good negative of the surrounding shipping, with the crowds of people on the quay, after which we packed and went on shore, where we were immediately swallowed up by the crowd, noise, and bustle that meant business.

MARK OUTE.

FIGURES IN LANDSCAPE AND GENRE.*

NEXT we come to Mechanical Reality, things which must not be attempted in photographs, because the camera can never confront them. These may be unattainable, either because they have no bodily existence, or because they always elude the camera.

* Continued from page 398.

I will first take an instance of the latter.

Mr. H. P. Robinson has told us, in *Landscape Photography*, p. 44, that he once wished to introduce a stuffed heron into a landscape, but finally decided against it, though apparently he could not himself quite understand the reasons on which he instinctively acted, and even fancied that he was making quixotic concessions to unworthy critics. Also, in Pall Mall the year before last there was an elaborate, very evenly lighted photograph of a stuffed lark leaving its nest. I heard the public admiring it, but it was most palpably unreal to the least observant expert. Now I do not believe that the critic's annoyance really rises from the fact that the bird is always badly stuffed, and does not accurately represent nature, but that the result is always unreal in that we never do see the wild bird at such close quarters, and with so much detail, as the photograph of the sham displays. We never see a heron standing quietly in a pool within a few yards of us, while we admire at our leisure heaven and earth and it. When we do get close to a heron, we come upon him suddenly, and all we really see is a confused flapping, a long neck doubling up, and a long pair of legs trailed rapidly away out of our sight. Or something unexpectedly goes up like a firework from under our feet, and that is all we see of the lark now leaving her grassy nest. From our knowledge of birds we may reconstruct and explain these scenes, but we see little more of them at the moment than of the separate positions of the legs of the trotting horse, and for the same reasons they are as unreal to us at close quarters. We do not see the bird at rest, because it will not stay; we cannot see its exact motions, because it flies off too rapidly. These facts, however, are not at first so obvious to us, because we can inspect birds at rest through a telescope, and thus form truer conceptions of them than of instantaneous movements, which we can only see in photographs and cannot verify in nature.

Secondly, come the subjects which are unreal, because they do not exist in the flesh. From what I have said it is natural that I should regard ideal studies as unmeaning in photography. An ideal study means an abstraction—a face or figure representing some one abstract quality or emotion from which all other sentiment has been withdrawn. How is this to be represented in a picture which we know to have been taken from a concrete human model, dressed in garments made by the costumer, and sitting in front of a portrait or R.R. lens? It is a contradiction in terms. Most of these studies, it is true, I suspect of having been taken first and named afterwards, and no doubt Resignation, Despair, or Patience on a monument could be adequately illustrated by most amateurs from their own collection of portraits. It may also be an agreeable excuse for exhibiting a beautiful woman in a fancy dress, posed in an attitude which displays her to advantage. But I do not see how these renamed portraits can claim to be ideal. We do not meet embodied qualities walking about in the everyday world; it is only in dreams like Spenser's "Faery Queen" that we encounter them, and into dreamland no material cameras are passed. No doubt some rare individuals may now and then be taken almost as representative of some especial attribute; but even with these the illusion is never perfect—no human being is a mere abstraction, but something much better and more complex. I believe that the best expression of an actual portrait is all that we can ever hope to render, and that only by a stroke of good luck added even to the best management.

On the other hand, I may add, parenthetically, that what unfits the camera for ideal work does not disqualify it for character-studies, in which individual character and details of personality are to be brought out as much as possible. These require skill in eliciting expression such as is only to be found in the best portraitists, and great dexterity and insight, but the results are among the surest title-deeds of photography to a place in art. A portrait may also be a good character-study, but the difference between these two is that the former must be a good likeness of the individual—must represent his habitual expression; whereas the character-study need only make the most of some picturesque expression of which the face is at any time capable, whether it be characteristic or not.

The portrait of an imaginary person, again, is another matter, and is as far astray as the ideal study. Mr. H. P. Robinson has told us of his conversion (by a critic) from this form of offence, and I need not dilate upon its depravity. It is, in its very conception, unreal to a fatal degree. Characters from Shakespeare—Rosalind, Portia, Hamlet; from Tennyson—Maud, Elaine, Rizzani; or from any of the poet or novelists, are absurdities in photography. They never lived on this dull earth; where could they have been photographed upon gelatine or collodion? At best the pictures could only represent some clever people acting the parts with complete success. The painter can depict them, because he sees them with the inner eye in the region of the imagination, where they were born and dwell; but even for him it is dangerous to approach a favourite hero or heroine whose worshippers have already formed for themselves a conception of their idol. Even the painter is apt to be dominated by his model. I think I am not mistaken in instancing out of thousands of greater failures a picture by a painter of the highest promise, Mr. J. W. Waterhouse, in last year's Academy, of the Lady of Shalott. It was admirably painted as far as skill went, and represented in a boat among reeds and willows a curious, fair-headed girl, to whom no objection could have been raised but for her pretensions to the Shalott title. My fancy is that the artist had been struck by certain possibilities in a model's face,

which were still to be seen in the picture, but the task had been too much for him. He had not been able to import enough imagination into his work, enough expression, enough transfiguration into the features, and it remained a clever picture, but never became the Lady of Shalott, with her lovely face and her weird carol.

Now, if this be frequently the case with the painter and his free-ranging art, how can the camera transform the model into the heroine? A photograph of the individual from whom a great writer had drawn a character would be most interesting in other ways; but even had he described the original as literally as he could, there would yet have been the medium of his imagination, which could not be interposed between the lens and the person photographed.

We may console ourselves by reflecting that these ideal and imaginary studies must have been most difficult, and it is something to be absolved from attempting the impossible. Think of the self-consciousness of the model! How could we get any one to pose for a representative of the Spotless Hero or the Perfect Beauty, of the Graces or of the Virtues? Unless, indeed, we tried "Piety," and adopted the suggestion made to Rogers when he announced that he would never have another portrait of himself painted except in an attitude of prayer. "Yes," said Sydney Smith, "I suppose with your face in your hat."

My censure for impossibility would fall on photographs of contemporary creations, of Anna Karenina and Daisy Miller, of Daniel Deronda and Richard Feverel, but into my other examples comes the further easily recognised voice of anachronism. It would, to vary a law phrase, be an impossibility upon an impossibility to have a photograph of an imaginary person who was supposed to have existed in the ages before photography was invented. Thus a photograph of Ivanhoe would be even worse than one of Aurora Leigh. But I will take the best instance possible of this class, a photograph representing Don Quixote, by Mr. Lake Price, to whom I apologise for picking out his work as an example. *Corruptio optimi pessima*. It is the best work on wrong lines which is the most misleading. You saw it here lately. A wonderfully good model was procured; the details were excellently carried out, and the composition and execution were beyond any praise of mine. But it was not, you knew it could not be, the real Don Quixote, and with that all its charm and all its value fell to the ground. Anachronism, of course, would equally upset photographs purporting to represent historical personages, even were models secured exactly resembling people as well known to us as Van Dyck's Charles I. or the Philip IV. of Velasquez.

So far I have spoken of anachronism chiefly as it used to be found in exhibition catalogues, in the pictures themselves it is mostly a matter of costume, for faces are not necessarily identified with any one period. In costume the temptation to anachronism is greatest because the necessity for keeping to dresses worn at the present day specially hampers photographers. Whole classes of figures and incidents are thus forbidden to us even as accessories, such, for instance, as were habitually introduced by Cattermole, or are now painted by Sir John Gilbert, to say nothing of the classical figures of Claude and Turner. Modern dress is notoriously a stumbling-block to painters, and it is even more vexatiously in our way, for to them it is sometimes possible to make something of the colour while adopting unobtrusively the most recent fashion in form, as in some of Mr. Whistler's or Mr. J. J. Shannon's pictures. We, on the other hand, can only render the cut and trimmings, and these fix the date within a few weeks if they are of the latest Parisian mode. To take an actual example, the other day I saw the date of a wedding group settled by the hair and dresses. Now, while on the one hand we avoid anachronism, on the other it is better not to indicate the date of our work too exactly. Although we cannot alter or make typical the face of a model, yet we can do something towards generalising a gown. I mean that it is better to use those simple, useful forms which have been worn for generations, and which do not attach closely to any one brief date. I may well be asked to name any instance of such extraordinary constancy and stability, but I think that most rustic garbs and the homeliest kind of women's dresses present no salient marks of recentness or temporary fashion. Such are the shawls once worn over the head by the lower classes almost everywhere, or the kerchief which at times took its place; but there are also classes of men and women whose dresses are adapted to their callings, and can thus never be widely varied. This is more especially the case with those engaged in the earliest occupations of all—the tilling of the land and the care of animals. The groom, the huntsman, the sailor, the hedger, the milkmaid, the haymaker, the butter-woman, the henwife, these types remain fairly constant, and these typical dresses are, moreover, a great aid in telling a story with clearness.

If costume is to be in fear of anachronism on the one hand, on the other it must never create a sense of incongruity. This is in part an offence against reality. A person in the finest clothes seen bareheaded on a moor strikes us as a phenomenon never seen in nature, if not actually inconceivable. But, on the other hand, the object may be only too real and too true, and yet, like an advertisement on the Great Pyramid, incongruous and discordant with the whole sentiment of the picture. There it becomes vulgarity, in so far as it betrays an imperfect conception of an ideal, a confusion in which an inferior note is struck, inconsistent with the higher harmony at which we aim.

Incongruity is perhaps the last of the errors which can be attributed to losing sight of reality. I may be told, however, that there are other

photographs, taken from actual models, which are no less unreal than those which I have been abusing; that elaborate groups acting out little episodes, such, for instance, as some by Mr. H. P. Robinson, are unreal, for had they been genuine and spontaneous, the persons engaged would have broken off when the camera drew up in front of them. "If it were so, it were a grievous fault," but the defect would only lie in the execution. It would only argue the absence of the master art, the art of concealing art. Their fault would be one which could be improved away, a self-consciousness or want of spontaneity, one which it would be possible to cure; the errors I have attacked are fundamental and can only be remedied by extinction.

I hope I have not wearied you, in regard to reality, with incessant repetition of a truism, and solemnly insisting that two and two make four, and that what is not within reach of a camera is, *ergo*, out of its reach. If I have not said what was too obvious, I hope that neither have I been insisting on a moral now useless. Certainly we are not at present overburdened with ideal work in our exhibitions, or with any pictures which are brimming over with imagination. There is a phrase, introduced, I believe, from America, of "flogging a dead horse;" and even to assist at that pastime is not exhilarating. But in the first place there are signs of life about the beast yet; few exhibitions are entirely wanting in photographs which transcend reality and possibility. But my metaphor has broken down, for I do not want the monster to get up and go on, but to die quietly. Secondly, I hope there will be much more activity of imagination in the future; and if this be so, it is important that the old misconceptions and stumbling blocks should be removed, and a start made on the right lines.

To resume. We established reality as an absolutely indispensable condition of photography, and on this ground we found that ideal studies, imaginative portraits, anachronism of dress or person, and incongruity were to be avoided; but incongruity, as we said, was partly a falling into vulgarity, and vulgarity we will now examine. GRAHAM BALFOUR, M.A.

(To be continued.)

ART: ITS BEARINGS ON PHOTOGRAPHY.

[A Communication to the Bristol Camera Society.]

It is the essential nature of art to deal with two distinct worlds—the spiritual or religious one, and the earthly one. Many clever writers have compared art with a book; in one sense it is a book, but one of the greatest importance, as its contents are for the greatest part historical—in fact, we may safely speak of art as a history, inasmuch as it deals so very largely with events past for many hundreds of years. But art is even beyond a book; it is, as it were, a camera, which, on looking into, we see a perfect image of the soul: its aspirations after which are noble and good, its mighty passions, its conflicts with evil, its doubts and its joys, and (using Whyke Bayliss' words) "like as a mirror to the soul, so art is also a record and a witness of the glory of the natural creation."

Again, art is a language: but not a language which is confined to England, France, Germany, or any other Continental power; it has its resting-place all over the world, even the barbaric races discourse with the language of art. Look at the Japanese and the Chinese, and see how they treat this universal language; certainly they localise it, but still it is readily readable. Take a bird's-eye view, and endeavour to see how and where it originated, and you will find how extensive the use of it has always been, and how at the present time it is extending—and extending on every side. Art may still further be described as poetry. It is actually the poetry of the soul, which rears at its best when health, happiness, and contentment are ours. It is impossible to produce it when trouble, care, and anxiety hold us, as it were, tightly bound. The mere attempt to produce a work of art, or soul poetry (if I may use the term), will be a complete failure (attempted under the last-mentioned conditions, as art belongs to the quiet moods of life).

E. J. Poynter, R.A., in one of his lectures, says, "The qualities of mind required to produce a work of art are two, the power of design and the power of imitation." He further tells that the power of design is also divided into two kinds, constructive and ornamental.

The fitness of Mr. Poynter's remarks is felt by us all, and I fear that the want of the qualities is regretted by most of us every time we have to undertake an art work of even small importance.

Take the first quality—design, which is always the foremost difficulty we have to encounter. In arranging our compositions we, of course, take into consideration the constructive value of our picture, or whatever art work it may be, and if we are sketching from nature we oftentimes find ourselves at a loss as to how to introduce or dispose of the objects before us, with which we are wishful to form our composition. We are apt to move about from place to place with the idea of blocking out little things which we think are likely to obtrude, and we endeavour to see other little things and effects which we imagine will be of more service to our work; but usually throughout all this manœuvring we are entirely ignorant of the constructive quality for which we should aim. In our endeavours to obtain a pretty picture we forget the different values which are required, be they composed of objects or lights and shadows. If we knew how to balance one object by another, or understood how each ray of light brought about its corresponding value in shadow, considerable time would be saved and better work be done.

The ornamental quality spoken of by Mr. Poynter does not bear so directly upon the composition of landscape as it does on figure composition or arrangement of conventional objects. Yet it is not to be entirely overlooked, even in landscape; its virtue should be felt by us in arranging our subjects to agreeably fill given shapes, or in the even distribution of light and shadow or again in the symmetry of certain lines, &c.

Now we come to the quality of imitation. In landscape painting this quality is of the greatest value; we cannot hope to accomplish any great work unless we most studiously copy the noble works of nature. Portraiture, of course, relies almost solely upon imitation, although other qualities are doubtless required. In still-life painting imitation supplies our every want. Before leaving this quality I should add that if the student carefully adheres to the rules laid down by nature his work is certain to be of high merit, for imitation, if cleverly done, is a sure means of giving realism, and true realism is one of the highest forms of art.

Realism should always be thoroughly displayed in all compositions; it will at once impress the mind of the critic with the story you wish to tell; it will give force and strength to your work, and will appeal to the sympathy of the soul; it will bring out the dignity of conception, the pathos of sentiment, and will give such character to your work that it will imprint on the memory the leading thought upon which you have based your whole mind.

After realism we come to idealism. If realism is one of the highest forms of art, then surely idealism is the highest.

A great painter once said, "My duty is sobriety. I could by two strokes of my brush make an expression of extreme intensity, but I should gain nothing by it, for it would not be nearer to nature. If I am to paint truly I must also paint soberly. Whilst I wield the power of producing mournfulness by turning down a lip, or merriment by turning it up, I must use it to walk with nature soberly, producing an effect real and ideal at one and the same time."

It has the power of giving a most poetic rendering of a most matter-of-fact subject; by it we can call smiles on the most solemn faces, and bring forth tears from eyes which a moment before brightly shone with joy. Again, idealism can be used for disposing of some of the harshnesses which realism is apt to give us, and, what is more important still, idealism deals with things spiritual. We are indebted to it for such glorious works as Michael Angelo, Raphael, Rubens, and others of the old school left behind for our study and admiration. The many beautiful conceptions of the Holy Family, and pictures of a similar class, are all due to idealism and its great co-helper, realism.

Simplicity also comes to the front when we are dealing with composition. The ancient Greeks in their compositions considered simplicity as a characteristic of perfection, and this idea is evidently carried out by our great artists and sculptors of to-day. If the Greeks were right, and we have every reason to believe that they were, then we must seek the same virtue for our works.

The one great point in favour of simplicity is that it prevents confusion; it gives to each figure or object a position, and there it has to remain; there is no stepping out of place and jumbling together, as we often see in pictures where simplicity has been overlooked. It acts as a means of quieting down, and gives an understandable meaning to the duller observer. This feature bears directly upon photography in several ways; first, in the subject itself, again in use of backgrounds, again in quality of light and shadow, and further still in the arrangement of light and shadow. The old-fashioned photograph invariably suffered from hardness of tone as well as exaggeration in the light and shadows, and generally failed to do more than remotely suggest what it attempted to represent; and even now those representing living persons are so stiff and generally uninteresting as to leave much to be desired, although they arrive at a stage considerably nearer to life.

Following on in the train of art, we encounter another great treasure called "expression." It would be interesting for us to see how the Greeks availed themselves of this treasure, and then to compare their use of it to the many uses to which it was applied during the period of mediæval art.

We find that they have one idea in common, that is, they take the human figure as the exponent of what they want to express. But beyond doing that they appear in a great degree to separate; the ideas of the Greeks, as it were, turned into a cold channel, whilst the ideas of the mediævalist turned into a hot one. This breach is mostly attributed to the different uses of expression.

Classic art relies upon its wonderful beauty and strength for whatever it has to tell, but it fails to tell as enough; it stops short at the very point where we are most anxious for it to proceed. Of life, the one great theme, it tells us very little; we have the manifestation of life, but beyond that we receive nearly nothing. The Greeks have left for our instruction and admiration objects of art which are perfectly invaluable, objects which in the smallest detail contain evidence of the most charming beauty, whilst the grandeur of mass and truthful simplicity of composition place their works in the foremost rank of art. But apart from their beauty, how do these wonderful works appeal to our sympathies? Personally, I feel a something which prevents any direct response as it were from my soul; there is a want of touch with our emotions which stops us from being able to accept them as of living people. Yet how is this! The forms are most beautifully and accurately executed, the proportions are unquestionably perfect, they possess every member of the body as we do, and yet there is that unfathomable something which causes us to stop short of acceptance.

What is this something? If it is not the fault of the form, then it must be the fault of expression. This is where I think the fault steps in; these most perfect examples of the sculptor's ability simply appear to us as stone because that one quality which gives life has been withheld. Sorrow and pain are only depicted on one or two examples; yet how can we feel compassion, or where is our sympathy, two most noble emotions, which act as a godly tie of one human being to another! There can be no compassion without the existence of sorrow, no deep sympathy without suffering. Yet the Greeks must have thought these unworthy subjects to receive perpetual remembrance in art. It was by the careful avoidance of such appealing emotions as these that the Greeks lost the one touch of nature which makes the whole world akin.

Now let us take a look at the art of the mediæval period, and we see for ourselves that, instead of being content with a cold grandeur, as were their predecessors, they go almost to the other extreme, and aim for life with all its passions. At the same time, they by no means overlooked or undervalued the grandeur of classic art, but they felt the want of touch with their sympathies, so straightway earnestly introduced into their pictures and statues that which had been previously left out.

Expression is the very soul of art. First, the expression of action, which gives force and meaning to our figures, and, in many cases, is even more im-

portant than the expression of the face. Take, for instance, a picture, statue, or photograph. Although each may be most cleverly handled in the execution, yet if expression is wanting how uninteresting they become. How accurately does even the quietest attitude express the character, spirit, and intention of the man, and how easily different passion are expressed and detected.

The power of portraying expression lies entirely with you. It is only for you to imagine yourself to be the very person whose position you are aiming to give, and if you can vividly realise the character you will naturally fall into the proper position.

Again, in the expression of the face, it is almost impossible for any master to help you. It is the artist himself who feels the very sentiment he wishes to express, be it either grief, mirth, fear, hatred, and so on.

I have heard it remarked that amateurs take better photographs than professionals. In landscape work this, to my mind is very true, and even in portraiture (that is, if we are to regard photography as an untouched print) the amateur is again in advance of the professional, for the reason that it too often happens that the professional photographer merely uses his negative as a kind of base upon which he is to set to work; and unfortunately he does set to work, with the result that the negative is retouched in such a manner that it is transformed from what was originally a photograph into a piece of stippled work, which either gives the portrait the appearance of polished marble, or is so coarse as to resemble a bad case of smallpox, and when we come to look for the expression—well, I will leave you to imagine how that has fared. I fear from what we are in the habit of seeing of professional work that it is more a matter of *l. s. d.* with him than sentiment, and yet it is the sentiment which gives a sterling value and an irresistible charm to our works.

The Archbishop of York, in a recent address on art, made the following remarks:—

"He sometimes saw in shop windows portraits of an elderly statesman, who had in reality furrows on his face, which were the wounds of the battle of life, the marks of victories won or conflicts gone through. But the photographer took care that none of these furrows should be seen. Touch after touch was made upon the negative, until at last the face was reduced to the condition of something that had been boiled. For himself, he declined to part with his wrinkles; they were the character of the man."

Look at the different faces we see every day of our lives. Often and often we pass faces by which contain the most charming beauty, so far as regularity of features go, yet we never take any further notice of them beyond giving them one passing glance. How is this? We are all anxious to admire beauty when we see it, and yet here we are passing it by without a regret. It is another case of classic art—there is nothing in the face that appeals to our sentiment. But meet a face which contains expression, and then we are not inclined to pass it by! No; we are like our fathers of the mediæval period, we have had our sympathies aroused, and we have become interested. It is only by this quality of sentiment that a firm alliance is formed with the affections in all works of art. And it is to strengthen this alliance that the photographer should make his aim. His productions are now used by the etcher, the engraver, and the lithographer, and are certain to be more used in the future than they are at the present time, for the reason that photography has two great advantages over the old system, namely, cheapness and greater accuracy of detail.

In conclusion, I would impress upon all present that art is nothing but divine sentiment. If you have not the power to ably produce a work of art, you have that which is next to it, you have the power to love art, and in exercising that love you are giving life to a divine passion which elevates to the highest degree.

JOHN FISHER.

Foreign Notes and News.

DR. M. ANDRESEN, of Berlin, has increased the already large number of recently discovered or recommended developers by yet another, to which he has given the picturesque name of Eikonogen, a name which would appear to be designed as much to keep secret its composition as to recommend it to the amateur in search of something new. This substance is said to possess considerably greater developing power than either oxalate or quinol, and to be only approached in this respect by pyro, from whose other unpleasant qualities, however, it is said to be free. Amongst other advantages claimed for it are cheapness, freedom from poisonous qualities, and durability, as it may be preserved for an indefinite period without fear of alteration.

M. GEORGES GUÉROUT has recently addressed an interesting proposal to the Académie des Sciences, namely, to bring the aid of photography to the help of the phonograph, for the purpose of reproducing before an audience listening to the delivery of a speech by the phonograph the gestures and changes of expression by which the speech was originally accompanied. He proposes, when the phonograph is set, turning to take a series of instantaneous photographs of the speaker, at intervals of one-tenth of a second. When the phonograph has been, say, thirty seconds in motion, 300 impressions will have been taken. After development they are arranged in a phenakistoscope, which also revolves in a period of thirty seconds. Now, impressions on the retina last for a period of one-tenth of a second, and as each successive impression is consequently presented before the previous one has completely disappeared, the effect would be to reproduce all the movements of the person in virtue of the principle of persistence. As there is no word which can be pronounced in less than one-tenth of a second, the gestures and changes of expression would exactly follow the words uttered by the phonograph. In this manner M. Georges Guéroult thinks it may be possible to store up and reproduce for the benefit of posterity, not only the words of an actor or speaker, but

also the quality which Demosthenes maintained to be the first and last requirement of an orator—his "action."

M. SCHLEUSNER writes to a French contemporary to put amateurs on their guard against too venturesome experiments. A friend of his, it appears, recently informed him that he had been attempting to improve the quality of albumen paper by immersion in an ammoniacal silver bath, and, having tried various substances without success, proposed to M. Schleusner to precipitate the silver with caustic potash. "*Figurez vous les résultats!*" exclaimed the alarmed M. Schleusner, and proceeded to point out that, had the ingenious amateur proceeded to carry his idea into practice, an explosive compound would have been formed capable of blowing him and his laboratory into fragments. He proceeds to warn amateurs against precipitating nitrate of silver with caustic potash in presence of ammonia, which produces fulminating silver; also against adding ammonia to sub-chloride of gold, which produces fulminating gold.

HERR OTTOMAR has demonstrated that it is possible to photograph a projectile during its flight, even with an initial velocity of 400 metres per second; the exposure occupied only one-tenth of a thousandth.

In reference to an article by Dr. Vogel, on the warping or expansion of gelatino-bromised paper, the editor of the *Photographisches Wochenblatt* remarks that, for photogrammetric prints, the drawback of expansion or contraction may be obviated by printing on the sensitive film at the same time as the image a network of parallel lines crossing each other at right angles and a centimetre apart. This may be done by tracing the network with a sharp point upon a sheet of glass coated with collodion stained with aurine.

EVERY one interested in optica has heard of the new glass said to be most suitable for telescopic and microscopic lenses, as manufactured by the firm of Schott & Genossen, Jena; but every one may not be equally well aware that the new Jena glass is the outcome of a series of experiments made by Dr. Abbé, Dr. Schott, and the late Dr. Karl Zeiss in the glass works at Jena, subsidised by the State. Formerly the only five substances used in glass making, the optical action of which had been examined, were silicic acid, potassium, sodium, lead, and calcium; but they resolved to set on foot experiments with a great many vitrifiable, inorganic substances, and from amongst them to choose the most promising for optical glass. Besides the five usually employed substances, other twenty-eight were incorporated in glass in proportions of not less than ten per cent. The result of the experiment being that the secondary spectral colours may be done away with in crown and flint glass by boric acid, which induces a specific contraction of the blue and a corresponding increase of the red end of the spectrum, just as fluorine, potassium, and sodium produce the inverse effect. Boric acid has now become the base for all sorts of flint glass in which diminution of the secondary spectrum is desired.

In *L'Amateur Photographe* Dr. Nelson-Pautier indicates the methods he employs to avoid in his positive prints the haloes which in negatives of interiors appear at the edges of the windows by which light enters. A luminous halo appears all round the window, and any details that may have been obtained disappear in the toning bath. He takes a piece of oiled paper the size of the front of the printing frame and cuts out a piece the size and shape of the halo (not of the window), which shows black on the negative. He then gums the sheet of paper at its four corners and sticks it in front of the printing frame. The part covered by the oiled paper will thus print in the same time as the uncovered part, and thus details will be got in the windows.

Our Editorial Table.

THE INTERNATIONAL ANNUAL OF ANTHONY'S PHOTOGRAPHIC BULLETIN.

New York: E. & H. T. Anthony & Co. London: Hiffe & Son, 93 Fleet Street.

THIS annual, which (the same as last year) is edited by Dr. A. H. Elliott on the American, and by W. Jerome Harrison on the English side, is not only out in time this summer, but quite maintains its reputation as a capital reading-book, containing contributions from writers on both sides of the Atlantic. To avoid jealousies, the editors have adopted the system of inserting these contributions in the alphabetical order of the authors' names. Looking over the various papers in this annual contributed by writers in the old and new worlds, we find many that are valuable and suggestive, and on every conceivable department of the art or "art-science" of photography.

In a humorous article on the *Art of Lying as applied to Photographers*, Mr. C. C. Verers, alluding to Oscar Wilde's remark that "lying, as a fine art, is fast falling into disuse," observes that Oscar must have been very imperfectly acquainted with photographers, and the statements made by dealers and manufacturers; and he cites examples, comprising photographs in natural colours, children taken instantaneously by a new process, permanent photographs (on albumenized paper); every make of plates has the largest sale in the world, every maker's lenses embody the utmost perfection in extraordinary definition, depth of focus, flatness of field, and are equalled by none, and so forth. Among the many good articles there is one by Dr. Clarence Woodman, of New York, on *Depth of Focus and Angle of View*, in which he expresses his preference for a wide-angle doublet of a focal length not less than the base line of the plate employed. The English editor, Mr. Harrison, contributes a series of notes on apparatus and books; while the American editor writes concerning the oxidation of sodium-sulphite solutions.

The work contains several excellent whole-page illustrations, with a list of all the American and English societies. It sells at two shillings.

In connexion with this Mr. Jerome Harrison writes:—

"Sir,—Will you kindly allow me to inform the contributors of papers to *Anthony's International Annual of Photography* that, as the author's copies, which will be sent to them, have to be specially bound, it is not possible to send them out till a short time after the publication of the ordinary edition? They will be despatched by parcels post as soon as ready."

CUT-OUT MOUNTS.

FROM Messrs. Mann & Son, London, we have received an assorted sample of cut-out mats for both stereoscopic and lantern transparencies. The forms of the apertures are diverse and faultless, this latter owing, doubtless, to their being cut out by hand. Owing to the high degree of magnifying to which they are subjected, it is of vital importance that the mats of lantern slides be perfect in every respect, and in these productions of the Messrs. Mann we have that required perfection. The shapes of the apertures are square, cushion, dome, and circular. The paper (black) of which the mats are made is smooth, firm, and quite opaque.

COLOURED GLASSES FOR ORTHOCHROMATIC PHOTOGRAPHY.

A SUITABLE kind of glass for use with the lens as a coloured screen when copying paintings, or any subject having strongly pronounced colours, by ortho or iso-chromatic plates has long been a desideratum, and this notwithstanding the directions for varnishing glasses, or staining the surface of the lens by collodion containing colouring matter.

We have just had samples, in four degrees of intensity, of coloured glass manufactured for orthochromatic photography by Mr. J. R. Gots, of 19, Buckingham-street, Strand, London, than which it is not possible to conceive of anything finer for the purpose. The colour is in the substance of the glass—that is, it is not flashed—and the transparency is of a high order. Both surfaces of the glass are optically worked, hence the perfect homogeneity of the plates. One is a very pale yellow, the others progressively advance in colour. Having a set of these glasses, one may now laugh at the most formidable oil painting or most variegated floral bouquet which is brought to him to be photographed.

The advent of these plates supplies a want.

RECENT PATENTS.

APPLICATIONS FOR PATENTS.

No. 9825.—"An Improved 'Washer' for Photographic Plates, Films, Prints, and the like." L. E. PERKIN, F. L. PERKIN, and A. RAYMENT.—*Dated June 15, 1889.*

No. 9469.—"Improvements in or relating to Instantaneous Shutters for Photographic Cameras." Communicated by G. Eastman. A. J. BOULT.—*Dated June 15, 1889.*

DEATH OF NORMAN MAY.—We are sorry to learn that Mr. Norman May, of Malvern, died on the morning of Wednesday, June 19, of consumption. He had been somewhat delicate for many years, so much so that two years that he had been unable to attend personally to business. His end has caused considerable excitement in Malvern, as many of his friends had built hopes on his recovery. On Tuesday he was driving and walking on the hills, in the evening he ate a good supper and went to bed in high spirits, the following morning between half-past seven and eight he breathed his last.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
June 24.....	North Middlesex Club	The Iron Room, Strand Green.
" 25.....	Great Britain (Technical).....	5A, Pall Mall East.
" 25.....	Bolton Club	The Studio, Chancery-lane, Bolton.
" 26.....	Burley	Bank Chambers, Hargreaves-street.
" 26.....	Photographic Club	Anderton's Hotel, Fleet-street, E.C.
" 27.....	Burton-on-Trent	The Institute, Union-street.
" 27.....	Halifax Photographic Club.....	Mechanics' Hall.
" 27.....	Liverpool Amateur	St. George's-crescent North.
" 27.....	Oldham	The Lyceum, Union-st., Oldham.
" 27.....	London and Provincial	Masons Hall Tavern, Basinghall-st.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JUNE 13.—Mr. T. E. Freshwater in the chair.

Mr. C. H. COOKE, in the course of some remarks on retouching, said that retouchers were wretchedly paid.

Mr. A. COWAN stated that retouchers were the best paid of any photographic employers when they were competent.

Mr. COOKE thought that they advertised to do work at too low rates.

Mr. W. H. PRESTWICH believed that small heads could be profitably retouched at three shillings per dozen, but not large heads.

Mr. COOKE said that photography is always untrue, especially in the deep shadows, and truly artistic retouchers can correct that without interfering with the portrait; photography always gives a want of detail in the shadows.

The CHAIRMAN remarked that he recently attended in Barnet a society of photographic amateurs which met once a week at each other's houses, and at the beginning of each year drew up and printed a programme for the whole twelve months, consisting of a list of subjects for competition during each month. The subjects were adapted to the particular season; for instance, last month the subjects were birds' nests and relics, and some of the competition pictures were very good indeed. One of them represented a nest in an old letter box. That which was selected as the best was from still life, and included two stuffed owls. In relation to relics, the best picture was that of Old Temple Bar, as rebuilt in the grounds in Hertfordshire of Mr. Menx, the brewer.

At the next meeting of the Association, Thursday night, June 27, Mr. A. Haddon will open a discussion on *Practical Methods of Testing Photographic Lenses*.

NORTH MIDDLESEX PHOTOGRAPHIC CLUB.

JUNE 17.—Mr. Humphries in the chair.

Mr. S. Quincey was elected a member.

Photographs of lightning flashes taken in the late storm were exhibited by the members, one (by Mr. J. Treadway) in which the flash had apparently struck a tree.

Discussion was raised as to the cause of the different varieties of flash, but no definite conclusion was come to.

A sample of the dusting-on process was shown, and the method of working explained, the one exhibited having been taken from a negative which was disfigured by spots from chemicals having been accidentally dropped on the film; but in the copy obtained by this method no trace of them was visible.

A new detective camera on the screw principle was shown, which was generally approved, the size being, when made in three-eighth and five-eighth inch wood and fitted with five-and-a-quarter-inch focus lens, 9 × 7 × 5 inches.

Mr. MARCHANT: How ought I to proceed to make a lantern slide from a half-plate negative?

Mr. HISCOCK: The best way is, if you have an enlarging camera, to use that, putting the negative to be copied where the enlargement would usually be, and the lantern slide in position where for enlarging you would place the negative; or with an ordinary camera it could be done by placing the negative from which you desire to obtain the slide upside down in a frame against the window, taking care that the film is inside, and then placing your camera inside and photographing it in the usual way.

Mr. WALKER stated that he had lately bought some waxed paper cloud negatives, which were very good, but that in printing there generally appeared on the print a number of greasy spots.

It was suggested that this might be due to too much vaseline (which was used to make them transparent) being left in the paper, and he might overcome this by heating them very strongly over a paraffin lamp or gas stove, or a safer method was to place them between pieces of blotting paper and pass a very hot iron over them.

All future meetings of the North Middlesex Club will be held in the Jubilee Hall, Hornsey-road, next to the Hornsey-road Railway Station on the Midland.

The next meeting will be on July 8, when Mr. Valentine Blanchard will demonstrate his platinum black process, and will commence punctually at a quarter-past eight. Visitors invited.

UNIVERSITY COLLEGE PHOTOGRAPHIC SOCIETY.

JUNE 11.—Mr. J. T. Leon, B.Sc., in the chair.

Paper read by Mr. E. S. Warrall on *Exposures* [this will appear in a future number].

A long and interesting discussion took place on the subject of the paper, for which the negatives taken by members on the excursions afforded excellent material.

A resolution adopting the metric system, as suggested by the Photographic Club, was put to the meeting and carried unanimously.

At the next meeting the Treasurer (Dr. Plimpton) will introduce the subject of *Phototype Printing*.

The next excursion of the Society will be to Elstree, on Saturday, June 29.

HOLBORN CAMERA CLUB.

JUNE 7.—Mr. E. CLITON demonstrated the method of coating dry plates, and briefly explained the action of developers upon them. The lecture was attended by about thirty-five members.

JUNE 14.—Mr. G. A. FREEMAN, B.Sc., F.G.S. (one of the Vice-Presidents of the Club), lectured on *The Chemistry of Photography*, explaining the action of light, the construction of lenses, the composition of developers, what chemicals will act together, &c.

JUNE 15.—In spite of dull weather, eight members visited Windsor, as arranged, and had an agreeable outing.

Photographers will be glad to know that shortly there will be a dark room available for their use at the Castle Hotel, Windsor, as the proprietor intends to fit one up as soon as the press of work caused by the Agricultural Show is over.

Messrs. C. L. Yates, W. Turvey, Alfred W. Dolland, and Thomas Fenaughty were elected members of the Club.

HACKNEY PHOTOGRAPHIC SOCIETY.

JUNE 13.—Mr. Henry Burton in the chair.

Mr. FENTON JONES (the Hon. Secretary) made an announcement with regard to his editing a *written* journal for the use of members only, wherein all the transactions of the Society could be recorded for future reference.

This proposition was enthusiastically received and carried unanimously.

An election of new members then took place *en bloc*.

Mr. C. Hoddle, of Mare-street, exhibited a neatly made camera constructed by himself.

The Chairman showed some very interesting photographs printed by him upon Pizzighelli paper. It was remarked that they were as good prints as could possibly be expected by that process.

Mr. Hodges also exhibited some excellent 12×10 prints both on platinum and silver.

Dr. ROLAND SMITH (who promised to read a paper at some future time) brought a very fine transparency taken on a Fry's German plate in proof of his contention that, although he never backed his plates, he was not troubled with this defect. The subject, an interior of a church, received one hour and fifty minutes exposure, and did not show any sign of the fault mentioned.

The CHAIRMAN then called upon Mr. J. Hubert (Vice-President) to read his paper and give a demonstration on *The Platinotype Process*.

Mr. HUBERT, having read a poem composed by him for the occasion, explained the process in detail, and proceeded with development by the hot-bath process. He also brought some samples of the Pizzighelli paper, which, however, bore no comparison with the patented process.

A member asked whether it was possible to print without the indiarubber pad.

Mr. HUBERT replied that he had occasionally done so without detriment, but thought it dangerous if the atmosphere were in a moist condition.

Another member questioned whether an ordinary good silver printing negative would be suitable.

Mr. HUBERT remarked, though it would be preferable to use a slightly denser negative, it was quite practicable.

Another member asked whether the prints dried much darker.

In reply, Mr. HUBERT said that the additional density was but slight; he further mentioned that he deprecated a gloss for platinotype prints, but would recommend the use of encaustic paste, which imparted a beautiful richness.

The prints developed were mostly recognised as local celebrities, and much admired. Mr. Hubert then passed the negatives round for inspection.

The CHAIRMAN complimented him upon his very able demonstration.

The meeting then adjourned to July 13, when it is hoped that another paper will be read by a gentleman of note in the photographic world.

BIRKENHEAD PHOTOGRAPHIC ASSOCIATION.

JUNE 13.—Mr. P. H. Phillips (Vice-President) in the chair.

Messrs. V. Pothergill, William Rowlandson, and E. O. Fricker were elected members of the Association.

Mr. J. A. Forrest exhibited some very fine pictures which he had taken at Bournemouth and Dolgelly.

The Hon. Secretary exhibited the competitive prints *re* Chester excursion, the first prize being awarded to Captain Ching, R.N., the second to Mr. G. Latimer, and the third to Mr. W. Tomkinson.

Mr. KENNEDY exhibited two half-plate negatives, one developed with hydroquinone, and the other with pyro and ammonia, both of which had the appearance of fog. He stated that several plates which he had exposed lately turned out the same way after development.

Mr. F. EVANS, in replying, stated that he had had similar results, and could only account for them by the plates being fogged before exposure. Sometimes he found that the slips of paper placed between the plates by the makers caused fog.

Mr. H. B. SHARPE then proceeded to practically demonstrate the process of *Transferyotype*, during which he transferred a half-plate print by squeegeeing on to a piece of opal; he next floated a film, half-plate size, from the paper and transferred it on to a piece of opal, enlarging the film during the operation to full-plate size, and showing at the same time the simplicity of enlarging by this process.

FROM Mr. Kenneth McK. Ross, Hong Kong, we have received a photograph of a flash of lightning of transcendent brilliance and dimensions. It was secured during a severe thunderstorm that passed over Hong Kong on the 29th of April. Mr. Ross has enclosed two extra copies, with a request that we give them to any scientific society to whom we think they would prove of interest. This we have done.

Correspondence.

23 Correspondents should never write on both sides of the paper.

DEFECTS IN SIDERAL PHOTOGRAPHS.

To the Editor.

DEAR SIR,—I am happy to see, by the number of THE BRITISH JOURNAL OF PHOTOGRAPHY for June 14, 1889, just received, that you are discoursing therein on a subject you are so well qualified for, both chemically and optically, and that you hold to that dual origination of the halated enlargement of the discs of certain stars when photographed in certain telescopes.

You have indeed just received a letter from a high astronomical authority, accusing the optical source alone as being at the bottom of the mischief, by means of light reflected from the back of the plate at some other angle than 90°, whereby your correspondent would explain ovality of star images increasing to astigmatism, and confusion of rays thrown towards the edge of the plate, to be then reflected still further outwards as they pass through the plate's substance diagonally up to the sensitive film again. A trick of light proposed to be rendered more indubitable by silvering the back of a plate, thereby getting the effect doubled, and then destroying it by coating the backs of other plates with *light-absorbing* materials, such as brown-red pigments, lampblack, and water.

All this is true enough for camera plates of large angular subtense at their objectives, and was found very useful thirty years ago by those who employed that test of patience, the tannin dry plate of the period. But if any astronomers are detected in the year 1890 publishing star photographs sensibly inaccurate in figure or place by reason of either not having used so well-known a remedy against halation at all angles as the above, or, on the other hand, childishly attempting to photograph too broad a field for the lens to cover without its breaking down in definition or altering in focal length towards the borders of the plate to an extent only too visible to any one's passing glance, let the justice of the nations now assembling for the star photography of the whole heavens be executed upon him as they will.

The particular optical cause, however, selected by your authority for denunciation is not, in all the cases I have seen from the observatories, even allowed there to attain really large dimensions, whether the plates have absorbent backing or not. So that your first theory, the chemical, strikes me as far the more important of the two difficulties which astronomers are now contending with. Even this one, too, they have largely reduced in dimensions of late years, for I can assure you, Mr. Editor, that some of the earliest photographs made of the nebula in Orion showed every bright star included as a huge, though faint globe—a something positively fearful to look at and ponder over its possible meaning; for the effect was universal and all over the plate, wherein the physiognomy of one star differed from that of any other merely in the size of its grey globe, which followed very nearly the brightness of its light as a point.

Wherefore that really appalling appearance of *swollen* stars, or blown bladders, when photographed in that day (by pure photography, too, be it remembered, which is usually considered to give out nothing but the naked truth) was due, as I ventured to hold at the time, to the wet collodion, and the particular sensitising salts employed for it, in that early day—or, in fact, to your chemical explanation. For the rise of the modern extra-sensitive *dry* plates, soon after that epoch, drove wet collodion out from all observatories, and then the stellar balloons in photographs quickly collapsed to far more moderate dimensions. Not perfectly though to points; so that there is still an evil influence of pretty considerable magnitude to be investigated, and exorcised if possible—firstly, perhaps, by comparing dry plates, successively sensitised by every likely salt under the sun, and trying them on stars with the same stellar instrument; and then by a little further examination of the optics to which telescopes are far more amenable, or in danger from, than are either portable cameras or small glass plates.

Should the telescopes, for instance, be dioptrics, and achromatised for eye-vision, the yellow rays of a star are brought up nicely to a point; but at the very same time the violet ones necessarily form a halo of that coloured light, or a residual and circular spectrum, which is in a manner photographically bound to represent a grey disc of light round about the star, if only exposed long enough; while, if the telescope's objective be achromatised more properly for the violet rays near G, and those rays be then brought well up to a point when in focus, yet not only will the red and yellow rays be left outside, making haloes of those colours, but the invisible rays of the ultra-violet, which have never yet been included in any achromatising formula, will be left outstanding at their end of the spectrum, and from their large spectral range are pro-

bably the chief delinquents in so spreading outwards the light of a bright star that no very faint one in its immediate proximity in a photograph is left unextinguished by it.

But should the astronomer, in desperation of ever completely curing all these lenticular difficulties, attempt to cut the Gordian knot of their entanglements by adopting a reflecting telescope without any lenses, and thereby obtain perfect freedom from all circles of differently dispersed light, rejoicing instead in a brilliantly intense white point of light, from a white star, when in the middle of the field—how soon he comes to appreciate that the optical field for sharp definition with that kind of telescope is so violently curved to short radius that only a very little of it can be utilised on a flat plate.

A mathematical theory was indeed recently published showing how, by altering the figure of the great speculum from parabolic to elliptical, or to just the other side of the simple and primitive spherical, a flat field might be obtained; but then with the loss (which the talented author did not prepare his readers for) of all fine definition from every part of the field, central as well as circumferential.—I am, yours, &c.,

Clova, Ripon, June 17, 1889.

PIAZZI SMYTH.

To the Editor.

SIR,—Having read with much interest the letter of Prof. Morize on the subject of *Sideral Photography*, as also the masterly articles in which the same subject is dealt with, both in the current issue of THE BRITISH JOURNAL OF PHOTOGRAPHY and in one of the issues of January, it has occurred to me that there is one aspect of the question—one possible explanation of the matter in dispute—which has been omitted from the controversy. The point at issue is, I understand, as follows:—Why, when the images of all stars produced by a photographic objective are mere mathematical points, do the brighter stars appear on the developed plate as discs whose diameter decreases with the brightness of the stars? Mr. Traill Taylor attributes this phenomenon apparently to two causes assisting one another: halation from the back of the plate, and lateral reflection of light from one particle of silver bromide in the emulsion to another. Prof. Morize seems to think the matter to be explained by halation alone, giving a somewhat elaborate explanation of how this takes place. Prof. Morize's letter would have been still more interesting had he actually tried the experiments he proposes and communicated the result, which his position as Astronomer of the Imperial Observatory, Rio Janeiro, would perhaps have enabled him to do. But even before we know the results of the experiments he proposes, we may, I think, conclude that his hypothesis does not explain everything.

Let us consider one of the cases alone which he handles—that of a star situated exactly in the prolonged optic axis of the objective. The light from this star on passing through the objective forms a cone of rays, which, when the objective is focussed for the first surface of the plate, has its apex at the point where the first surface of the plate intersects the optic axis; it forms a second cone whose base is the second surface of the plate from which it is reflected back, and on intersecting again the second surface gives rise to the disc in question. Now, from this it would follow, first, that the disc appearing on the negative would increase in diameter the thicker the plate used; secondly, that its size would depend on the angle of the cone of rays, i.e., the focal length of the objective; and, thirdly, that the same thing ought to occur with stars of the very smallest magnitude, and though the illumination of the disc formed by their light might be too faint to show under ordinary circumstances, still by employing larger exposure or a more powerful developer they would ultimately appear also as discs. These are, I think, correct deductions from Prof. Morize's hypothesis. Do they agree with actual facts?

Mr. Traill Taylor's suggestion seems to be much nearer the mark, inasmuch as the lateral reflection from point to point of the emulsion would naturally extend further the more strongly the point from which it originated was illuminated. I do not, however, feel sure whether the optical continuity of the emulsion is sufficiently imperfect to permit of this irregular lateral reflection; and then there comes in the fact that a body which is decomposed by light usually only reflects those portions of the light which are inactive on itself.

May not the true explanation be somewhat as follows? The decomposition effected by light on silver bromide, or any other chemical compound, is universally considered to be due to a vibratory action set up within the molecules of the body in question by the undulatory motion of the waves of light. The light, in fact, shakes the molecules apart, and this action increases in intensity the brighter the light, i.e., the greater the amplitude of its vibrations. There seems to be no doubt that this vibratory action occasioned in the particles of silver bromide is propagated from one particle to another beyond the point actually influenced by the light, and this action will extend further from the point of origin the greater the amplitude of vibration at that point, just as the widening circles in a pond extends further from the spot from which a stone has been dropped into it the greater the height from which the stone has fallen. A photographic plate exposed to the firmament behind an objective is really being subjected to a decomposing vibratory action at a number of points, but the amplitude of the vibration varies at these points with

the brightness of the star. Is it not natural that the decomposing action occasioned thereby would extend the further from its centre of origin according as the amplitude of vibration at these points is greater or less, and so produce discs corresponding in size to the brightness of the star?—I am, yours, &c.,

R. N. LUCAS.

8, Featherstone Buildings, W.C.

PRETSCH'S PHOTO-GALVANOGRAPHIC PROCESS.

To the Editor.

SIR,—In an editorial under the above heading, in the issue of the 7th instant, reference is made to a previous inquiry of mine as to the neglect of the above system of process printing. Therein the difficulty of depositing the copper on a wet gelatine relief, owing to the solvent action of the acid sulphate of copper solution, is mentioned, and the necessity imposed by this degradation of much and expensive handwork on the copper plate is justly pointed to as one objection to the process.

The writer is apparently unaware that practically this difficulty was avoided (although probably this fact has not been published) by taking a mould of the relief in a mixture of, I believe, lampblack and guttapercha melted by heat, from which a cast being taken, was used as a matrix for the deposition of the copper printing surface.

Subsequent experiments were made by Messrs. Corelli Bers and Theophilus Ward with the object of producing a gelatine relief which could be safely used direct for the electro-deposit. I have been shown an old formula-book by the first-mentioned gentleman, in which there are some notes describing their method, in which, after development, the relief was flooded with spirit, subsequently blotted off, and coated with bronze powder, then treated with a twenty-five grain solution of nitrate of silver, the copper being deposited on the silvered surface. Prints by this process were successfully produced, and some photographic portraits of the Royal family were executed by it for the late Prince Consort, who was much satisfied with them. In the manuscript-book above mentioned I observed a further note that the addition of a considerable amount of albumen to the gelatine renders it free from action of the acid sulphate. I am inclined to think that the real reason of the death of these processes was one mentioned in the issue referred to herein: "That the period was not then ripe for mechanical processes," and also the jealousy with which the profession then regarded them as likely to interfere with their regular trade.

HENRY E. DAVIS.

Exchange Column.

. No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Wanted, pair of stereoscopic lenses in exchange for 18 x 16 enlarging camera (focussing from ten to about sixty inches) or other apparatus.—Address, ARTIST, 30, Radcliffe-road, Fulham, London, S.W.

Answers to Correspondents.

. Communications relating to Advertisements and general business affairs must be addressed to "H. GREENWOOD & Co.," 2, York-street, Covent Garden, London, W.C.

All matters for the text portion of this JOURNAL, including queries for "Answers" and "Exchanges," must be addressed to "THE EDITOR," 2, York-street, Covent Garden, London, W.C. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.

PHOTOGRAPHS REGISTERED:—

Thomas Protheroe, Bristol.—One photograph of the late Mr. Samuel Cook, Professor of Music.

J. Browning, Exeter.—Two photographs of Sir Thomas Acland.

Miss M. Corrie, Alresford.—Two photographs of For Memorial Chests in Winchester Cathedral. One photograph entitled "The Batter Land."

W. B. S.—See our "Editorial Table" notices in this number.

Col. J. B. AMOTT (Quebec).—See article on the subject in present number.

CARSTIC.—In answer last week, instead of "acid caustic potash" read "and caustic potash."

B. C. D.—So far as we are aware, paper specially prepared for Woodburytype printing is not an article of commerce in England.

DR. W. RICHARDSON wishes for information respecting Coventry's plate-coating machine, described in our ALMANAC for 1887, page 277.

F. SCOTT (Fulham).—Inattention to our plain instructions respecting such communications is almost invariably attended by delay. Read the notice at head of this column.

X. X.—You will find formulae for reducing agents on page 569 of the ALMANAC for 1889, and on page 607 of that for the current year. Both of these are simple and good.

D. M. PIERSON.—The best negative varnish which can be applied to the negative while it is cold is one of dammar and benzole—about thirty grains of the resin to the ounce of solvent.

READER FROM THE FIRST.—We are requested to ask you to write to Messrs. F. M. Perkins & Sons, Seaford-street, King's Cross, from whom detailed particulars of their means of producing cold may be obtained.

E. C. MAY.—There is rather more difficulty in stripping when hydroquinone is used; but the difficulty may be overcome by immersing the negative in dilute hydrochloric acid—thirty minims or so to the pint of water—after the negative is developed.

VIGNETTE writes: "Will you please inform me, through the medium of your 'Answers to Correspondents,' the way to produce vignettes with dark backgrounds instead of white ones?"—Several methods of producing this kind of picture will be found in a leading article on page 465 of our last volume.

BICHROMATE.—No work on ceramic photography has been published of late years. The last was a small manual by J. Solomon, 22, Red Lion-square, Holborn, London, which contains much practical information. It is quite possible to use gelatine instead of collodion as a foundation for the image.

GWENT.—We do not know of any lens which, having such a focus and working with such an aperture as yours, will work any better than it. You might try some of the cemented rapid doublets, but their aperture would be smaller than that with which you are working, and hence their action would be slower.

S. WARRELL.—You are a little mixed between the two processes. In the collotype process it is a fatty ink that is used, and in the Woodburytype the gelatinous one. The printing in the former is done from a gelatine film, and in the latter from the leaden mould. The above clears away the mystery.

DOT.—If you are sure that the dark slides are in register with the focussing screen—and the fact that all your other lenses yield sharp negatives with the same camera goes to prove that they are—you should certainly return the lens to the one who supplied it. Clearly its optical and chemical foci are not coincident.

A. REID complains of yellow stains on some of his bromide prints, and sends us an example.—The stains are undoubtedly due to imperfect fixation—too short an immersion in the fixing bath, or the solution too weak. The stability of bromide pictures is too frequently jeopardised from want of care in this direction.

J. WRIGHT.—The want of sharpness in the pictures sent is not due to the shutter jarring the camera, but from the movement of the objects themselves. All the stationary objects are sharply defined, but it is the moving ones only that are blurred. The shutter is not rapid enough for such work unless it can be made to act quicker.

A COUNTRY PROFESSIONAL.—You are quite right when you say that the prices charged by some photographers for portraits are far too low; but we fail to see that this is a question that can be dealt with by the Photographic Section of the Chamber of Commerce. Every one has the right to charge what he chooses for his work, and no law or power can compel him to charge more.

H. A. H. HUTCHINSON.—1. The proportion of carbonate of ammonia in the fixing bath is not very important; about a quarter of an ounce to the pint will answer.—2. Probably you have used too much bromide in the hydroquinone developer, hence the hardness.—3. You would do better to keep to the formula; the omissions you have made will account for the yellowness.

J. W. L.—1. We consider the camera named to be reliable and efficient; we say this after having had considerable experience with it.—2. Quite suitable for street scenes.—3. No finder, and, in our estimation, not necessary.—4. Any lens will do for rapid work that has a moderately large aperture. In bright weather one bearing a stop equal to $f/15$ will take views with great rapidity.

A. S.—1. If the silver is not precipitated from the old fixing baths by "liver of sulphur" it shows that the latter is at fault; probably it is decomposed by keeping. Sulphide of potassium quickly decomposes unless carefully protected from the atmosphere in well-secured bottles.—2. Citrate of soda is formed, which does not retard the action of the toning solution so much as citric acid would do.

W. CAVE.—Your idea to use a long-focus lens so as to secure good covering power with a large aperture is very good, but you must bear in mind that a long-focus lens employed on a small plate means a very narrow angle of view. A seven-and-a-half-inch focus lens on a quarter-plate detective camera will include only a very limited angle—far less than is usually obtained with this class of apparatus.

F. W. MORGAN.—We have not time to make such an examination of the cardboard as would be necessary; any analytic chemist will do so for you. You can, however, arrive at a fairly good estimate of its suitability for silver prints by steeping it in water, blotting it off, and then pressing it in close contact with the face of an unmounted print for a few days, afterwards noting if any change has taken place in the print.

BEX writes: "I want to make some enlargements, about 17×21 ; I have made some trays in wood covered with mackintosh; will you kindly tell me if I can put iron, acid, hypo, &c., in these without danger to the paper? I find the price of glass here (Bex, Switzerland) prohibitive. How can I make a negative printable that has stains (from paper getting wet) completely through the film?"—The mackintosh will not act injuriously. If the stains are merely superficial, try Mr. Werge's panacea given in a recent number.

W. SHAWCROSS.—We cannot speak as to the permanence of the prints, so, as far as we can see, beauty rather than any enhanced degree of permanence forms the claim for consideration. You are correct in your hypothesis.

G. J. W. writes as follows: "A customer left a water-colour drawing with me to copy; unfortunately, a drop from an oil can has fallen upon it and made the paper at that part nearly transparent. Is there any means of extracting the grease without injuring the colours?"—The best plan will be to moisten the grease spot with clean benzole and then dry with blotting paper. By repeating this operation several times, both back and front, the grease may be taken out without injury to the water colour. It is scarcely necessary to say that both the benzole and the blotting paper must be scrupulously clean.

ROMEO says he fails completely in carbon printing, for, "after sensitising and drying the tissue, although it is used on the following day, it will not wash away in the warm water, and sometimes the tissue will not hold on to the support, but comes off directly it is put into the warm bath. The tissue is sensitised in a bath of one ounce of bichromate of potash and twenty minims of ammonia in thirty ounces of water for three minutes, then hung up in a dark room, where it dries in about six hours. A friend suggested that a piece of the unexposed tissue should be tried in warm water, but it would not dissolve."—It is clear that the tissue is insoluble, though if it be sensitised and dried under the conditions stated the difficulty is not easily accounted for. We should advise that the tissue be tested for solubility in warm water before sensitising, and if it is all right, then the trouble may be assumed to arise from the after operations, though this does not necessarily follow.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—Technical meeting, Tuesday, June 25, at eight p.m., at the Gallery, 5A, Pall Mall East.

PHOTO-MICROGRAPHS.—Among those who are engaged in this fascinating department of our art is Mr. George H. Slight, who has sent us several examples, showing his progress in this direction. These include scales from the wings of moths of the less-known variety of these pretty pests, skin of human scalp, a section of *Dendrobium*, transverse section of ovary of poppy, and anchors and plates of *Synapta digitata*. We have to compliment Mr. Slight upon the excellence of his work.

NEW STYLE OF MOUNT.—Messrs. Percy Lund & Co., Bradford, have sent us a new style of mount introduced by them. The board is extra thick, and in the back layer of which it is composed is cut a slip which may either lie down flat, sunk as it is in the mount, or be bent out to serve as a supporting strut when it is desired to place the picture erect. The pretty photograph which adorns this really excellent mount is by Mr. Harold Baker, "Photographer to the Archaeological Section of the Birmingham Institute," and the "Archaeology" here depicted is—a handsome young lady! O Mr. Baker, how can you be so ungallant? It is termed the Antos mount, and has burnished gold bevelled edges.

PHOTOPEL.—When we wrote concerning these useful pellets last week we did so on the assumption that they were composed of pyrogallic acid with which had been compressed some of the other ingredients which go towards forming a perfect developing compound. We are reminded by Messrs. Wyleys & Co. (although we had previously made the discovery ourselves) that the pellets have hydroquinone as a base, associated with restrainers and other substances. Pyrogallol, they tell us, has been supplied in tablet form before now, a fact of which we are well aware from having been the first to publish elsewhere this useful application by Dr. George Sindair of the compressed pellet idea to photographic purposes. This, as Messrs. Wyleys & Co. say, is the first time two or more substances have been compressed in pellet form for photographic use as a developer, and we learn that the idea forms the subject of a patent by Mr. H. W. Jones, F.C.S.

FIRE IN DERBY.—A STUDIO BURNED DOWN.—About half-past eight on Tuesday morning a fire broke out at the photographic studio of Mr. William Ethelbert Henry, St. Peter's-street, formerly in the occupation of Mr. W. E. Swift. About an hour's hard work by the fire brigade sufficed to subdue the flames, but not before the studio was completely gutted. The building, which stands at the rear of a number of shops in St. Peter's-street facing the spot, was glass-roofed, and its contents proved to be of a very inflammable nature. The cause of the outbreak is at present unknown, but, from a statement made by Mr. Henry's assistant, it would appear that he was on the premises at eight o'clock for the purpose of taking the photographs of two ladies, and whilst in the dark room he struck a match. He afterwards left the premises for a short time, and returned to find them in flames. Mr. Henry was at the time in Torquay, and it is, therefore, not known whether the stock was insured, but in any case the damage is sure to be very considerable, a large number of negatives being destroyed or spoilt by the water. The exact amount of the damage done, however, has not yet been ascertained.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1521. VOL. XXXVI.—JUNE 28, 1889.

TONING BY A BRUSH.

SOME, if not all, of those who have become photographers since the introduction of gelatine plates may not be aware that the development of a negative used to be effected, not in a dish, as now practised, but by holding the plate between finger and thumb and pouring over the surface enough of the developing solution to wet the surface and form a layer over the film; and with wet collodion plates such is still by preference the method adopted.

The toning of paper prints, too, is invariably carried on in a dish, and for many reasons it is undoubtedly the best way by which to effect the desired end.

Still there are circumstances easily enough conceivable under which it might prove desirable not to waste upon the toning of, perhaps, a single print any more gold or platinum solution than can be avoided. To such the method of applying the toning solution to the print by means of a brush will prove acceptable, and it is here only recommended as an expedient for him who, having only one or two prints to tone, hesitates upon the desirableness of making up for that special requirement enough toning bath to serve for a dozen more.

While writing, we have before us a cabinet photograph, well toned to the edges, which was treated in the following manner: After being removed from the printing frame it was placed in water and subjected to three changes in order to remove most of the nitrate of silver. A clean piece of paper about the size of the print was then made wet and spread out upon a glass plate, and upon this the print was laid, face up. A watch glass having been nearly filled with water, previously rendered slightly alkaline with sodium carbonate, one drop of a rather attenuated solution of chloride of gold was added, and by means of a camel's hair brush this was applied to the print, care being taken to apply it uniformly.

The toning action quickly commenced and was allowed to proceed to a dark purple, after which the proof was rinsed and transferred to the hypo fixing bath. There being still some of the gold solution left in the watch glass, a second print and the only other one prepared for the experiment was treated in like manner and with similar results. Although this trial was made with a camel's hair brush, there is little doubt that a Buckle's brush or a Blanchard's brush would answer the purpose as well, if not better. The former of these was in the early days of photography much used for spreading solutions on paper on which negatives were then taken.

It consists of a piece of thin glass tube of a diameter somewhat exceeding that of a common pencil. Measuring two in our possession, we find one to be one centimetre and the other two centimetres, or three-eighths and six-eighths of an inch respec-

tively. Into one end of this is drawn, by means of a bit of string, a tuft of cotton wool, a moderately large head or bunch of the cotton being allowed to remain outside the end of this extemporised brush. Instead of a string for drawing the wool a sufficient distance up the tubular handle, one of ours has a silver wire with a hook at the lower end and a loop at the upper end.

The Blanchard brush consists of a simple strip of glass cut to any width desirable for the special purpose to which it is to be applied, one or more thicknesses of Canton flannel or swansdown being then bent over the end and secured in its place by an indiarubber band.

PHOTOGRAPHS AND THE POST OFFICE.

A CORRESPONDENT in another portion of our columns raises a question of very considerable importance which we are surprised not to have had brought forward before. It is the question of responsibility for pictures damaged in transit through or while in the hands of the Post-office officials. Is the sender to suffer the loss, the receiver, or the Post Office itself? It is not our purpose to act as consulting solicitors in the matter, but a few points that have on previous occasions been brought before us may with advantage be here alluded to. Our present purpose is less to settle a question that is in a lawyer's province to deal with than to show how a photographer may help himself. It may be taken as an axiom that in all cases where professional photography comes in question it is always better to suffer a little loss than to raise a discussion that will tend to personal discomfiture: so that, though it might be well to know how the "law of the land" would treat such questions, the less frequently it is appealed to the better.

As regards the Post Office itself, its responsibility is clearly defined in the *Post-office Guide*, published quarterly, and also, sufficiently for all practical purposes, in the little penny book purchasable at any post office in the kingdom. For anything sent by letter post the Office does not hold itself responsible at all. By registered letter it does now to a limited extent, though a short time ago, quite contrary to the prevailing idea, the registration of a letter gave no power to gain damages for its loss, it only insured extra care being taken of it during all its journeys from sender to receiver. Registration now in effect insures a packet so sent in addition to this insuring of special care being taken. Next we have the Parcel Post, by which, at what is practically a booking charge of three halfpence, in addition to three halfpence per pound weight as a

carriage rate, parcels can be sent anywhere in the country; and, further, by paying one penny extra, can be insured for five pounds, or ten pounds when twopence is paid. Here, again, error is often made; when the parcel is not over the value of two pounds the money paid to the Office for the carriage acts as an insurance premium also. This is not sufficiently borne in mind either by the public in general or the photographer in particular. When we turn to the question as to who is to pay when the Post Office cannot be brought in as liable, we come at once to the solicitor's province, and we are face to face with technicalities. It is, however, certain that the more obliging a photographer is in packing up and sending off all his pictures post free, the greater is the probability of his having to pay if damage is done. If no one, for instance, sent photographs by post unless when he was specifically requested so to despatch them, the person who orders the pictures is incontestably liable. When, on the contrary, it is the custom of the establishment to send out post free all *cartes*, cabinets, &c., we are of opinion that the question who had to pay for damages would be settled, not broadly on its apparent merits, but by some technical point turning almost upon a quibble of words as to what was said about the matter at the time the pictures were ordered.

Dwellers in the metropolis will feel little concern about the matter, but when it comes to photographs sent out of town to the country, or from any studio in the kingdom to another point reached by rail being irretrievably damaged, every one would be on the alert. In some directions, to our positive knowledge, there is more danger than others; in those neighbourhoods, in fact, where the mail train does not stop to pick up or drop the letter bag, but does it all by means of a mechanical contrivance, which causes the bags to be received into a network attached to the train or to throw them out in a similar manner, damaged pictures are certain to follow. If a packet containing, say, a dozen cabinets—strong stout card—enclosed in a bag or case should happen to be in a prominent position when the letter bag drops upon the netting, a force of many hundredweights is applied, and the cardboards will give way. Large numbers of pictures damaged in this manner have been brought before us, and the senders have been unable to obtain any reparation for their loss from the Office. We strongly recommend every photographer who has to send pictures in such directions either to take care to have responsibility repudiated, or better to send by Parcels Post, the postal fee for which, as we have said, is an insurance of itself.

We would draw special attention to negatives. We have been informed by a Post-office official that the demands for compensation have been so great for loss of negatives that the office will decline to make good the loss if the parcel bear no outward mark or marks suggestive of misuse. We would specially call attention to the clause that the making good of a loss is not a right, but a special "act of grace."

Finally, let us caution our readers when they are sending pictures to see that they are properly protected and secured. No single photograph should be sent in a letter, for the stamp of the sorter comes down with such weight that a sheet or two of paper is no protection whatever. We should think that annually there must be tens of thousands of pictures so injured. To sum up. If photographs be carefully packed and protected, and sent by Parcels Post, when travelling along a line on which the special apparatus is used, or in any case where special care is wished for, we believe that the losses would be so few that there would never be a chance of a discussion being initiated.

PYROGALLIC AND HYDROQUINONE DEVELOPMENT

THE steady everyday experience of the past few months with hydroquinone seems to be gradually tending in all directions to a better and truer recognition of the respective merits of the old and new systems than previously existed. On the one hand, we were formerly met with statements amounting to utter condemnation of hydroquinone; on the other, to such fulsome praise of its good qualities that one was inclined to wonder why or how the world generally had tolerated pyro for so many years, after the first mention of hydroquinone as a rival.

There is certainly at the present time every evidence of a disposition to view the relative merits of pyro and hydroquinone from a more judicial standpoint than was the case twelve months back. This is due no doubt to the fact that the newer agent has been carefully studied by itself, as well as in comparison with pyro; or, in other words, its action has been investigated in conjunction with different alkalies and under all circumstances with a view of obtaining the best possible result from it, instead of, as was at first the practice, pitting it against pyro under identical conditions. It has thus come to be recognised that the two substances require to be handled quite differently in order to secure the best results, and that when so employed each has its good points—points which for some purpose or purposes render it preferable to its rival—while neither can be said absolutely to be the better for all purposes. In fact, pyro will retain its place in the photographic laboratory, while hydroquinone, which has already obtained a good footing, will, undoubtedly, continue to improve its position.

Perhaps the most important variation in the mode of using the new agent has been the substitution of the fixed caustic alkalies for the carbonates originally employed in conjunction with it. This is the keynote of the whole matter, and recognises in the most unmistakable form its difference from pyro, since the latter has been proved to be practically unusable with caustic alkalies except ammonia. So far as the carbonates are concerned it has long been recognised that they are perfectly available for use with pyro, though it has been only in recent years that they have secured any great degree of popularity. Ammonia solution, on the contrary, which has been from the earliest days of alkaline development the favourite, if not the only form of alkali in practical use, was from the introduction of hydroquinone recognised as producing with the new agent results inferior to those obtainable with the carbonates, and without doubt it was due to the persistent ignoring of this fact, pointed out by some of the earlier observers, that hydroquinone for a long time obtained such scant recognition.

But even after the adoption of the carbonates of soda and potash, the slowness of development of hydroquinone caused it to be held at a distance by many workers, who, so far as quality is concerned, preferred its results to those obtained with pyro. The addition of bromide, too, though in a great measure superfluous, was persisted in, and added still further to the slowing of development, so that from one cause or another the general adoption of hydroquinone appeared, to say the least, improbable.

By the introduction of caustic soda or potash in place of the carbonates, however, an entire change was effected. Not only was the initial energy of the developer increased, but the employment of bromide by those who prefer or insist on it was rendered possible without increasing the time occupied in development any more than would be the case in using

pyro. And add to this, the character of the image produced and the control over the action of the solution were in every way improved. As a matter of fact, indeed, the substitution of the caustic alkalis placed hydroquinone very nearly on the same footing as pyro so far as energy is concerned, with the advantage of greater cleanliness in working. But pyro, without doubt, remains the more vigorous agent, is more plastic, if we may use the term, in its action, or more under control, especially in cases of under exposure, and certainly offers far greater facilities for modifying the colour and general character of the image than is possible with hydroquinone.

The latter, however, possesses one feature which is of the greatest value under some circumstances, namely, its latitude in the matter of the quantity of alkali that may be added without producing fog. This would at first sight appear to be a recommendation in favour of hydroquinone in cases of under exposure, but such is not so; "thus far and no farther" appears to be the motto of hydroquinone with a given exposure, no matter how the alkali may be increased. But when it is a question of producing density or vigour of image on a film ordinarily deficient in that respect, hydroquinone possesses distinct advantages over pyro, in that it permits an almost unlimited quantity of alkali to be used. But the treatment must not be applied in the same manner as with pyro, that is, in a gradual manner, or by successive additions of alkali. Curiously enough, this style of procedure, after a certain point is reached, ceases to have any effect whatever with hydroquinone, though with pyro it is the only effective mode of working, unless the exposure and every circumstance have been accurately gauged. The only plan to follow is to commence development with the full or almost the full strength of alkali intended to be used, and this may be accompanied where special density is required by an increase in the proportion of hydroquinone. Though restraining bromide is entirely unnecessary under normal circumstances when employing ordinary proportions of caustic alkali, and actually detrimental in conjunction with the carbonates, it should never be omitted when the proportion of alkali is pushed to the extreme. As already stated, the marked "slowing" action produced when the carbonates are used does not occur when the alkaline hydrates are substituted, and the restrainer can—may, must—be used without disadvantage.

In summing up the respective advantages of the rival developers, so far as negative work is concerned, the balance is difficult to strike, but, perhaps, is in favour of pyro. This, without doubt, offers greater power in bringing up detail in an under-exposed picture than hydroquinone, which, however long applied, appears incapable of passing a certain point, no matter what quantity of alkali may be used. So far as mere cleanliness of working and freedom from stain are concerned, there is now fortunately little really to choose between the two if properly used, so that in striking the balance, the leaning towards latitude in development seems to turn the scale in favour of pyro.

It has been stated—but with a marvellous want of thought or of knowledge, it seems to us—that hydroquinone is the developer for transparencies, but not for negatives. So far as transparencies are concerned it is certainly capable of producing beautifully clean and in every way satisfactory images, of practically only one tone however, namely, black, or shades thereof. Pyro, on the other hand, is capable of producing the same cleanliness and quality with the additional advantage of variety of tone, and this, coupled with the extra control in development, turns the scale again, we think, in its favour.

If the statement quoted in the preceding paragraph had been applied to hydroquinone in conjunction with paper positives we should have been prepared to fully endorse it, for here, we think, it cannot be denied that a decided advantage, and no small one, exists. In colour, in cleanliness of working, in gradation, and, in fact, in every essential to the production of a good print hydroquinone is far and away superior to pyro, and it is a serious question whether it will not, with a little more study of its application to the particular purpose, completely displace ferrous oxalate.

In fact, to conclude, we may express the opinion that while hydroquinone grows in favour pyro retains as good a position as it formerly did, and the only developer that appears to be doomed for practical purposes is ferrous oxalate, which may have for positive work to give way to hydroquinone, as it has already done to pyro for negative purposes.

An interesting question, in the minds of those who devote attention to the subject of permanence, has always been the relative proportion of the noble metals in the gold-toned picture. The same question has again cropped up with reference to Mr. Blanchard's new process. Now, the toning of a silver print is simply the substitution of the silver in the image, wholly, or in part, by gold or platinum, as the case may be. Of course, if the substitution were complete, the image would be composed entirely of the gold or the platinum. However, in gold toning, the action, in practice, is never carried on to this stage, on account of the resulting colour of the picture. But in the case of platinum it may be, under certain conditions.

THE relative proportion of the metals of which a photograph is composed can, of course, be ascertained by quantitative analysis, but this is a thing beyond the scope of the average photographer, particularly when dealing with a single point or so. Even in the hands of an expert, when working on so limited a scale, absolute accuracy is always somewhat dubious. But if a large number of prints can be dealt with the thing becomes simple enough and the result reliable. Here is a case by way of illustration. Some few years back Mr. William Bedford took a large quantity of toned and finished prints—a hundredweight, if we remember rightly—and burnt them. The ashes were then reduced in the furnace in the ordinary way, and the resulting nugget of metal proved, on assay, to consist of 175 parts of gold to 435 of silver. Hence, in this instance, the image was composed, as nearly as possible, of one part of gold to two and a half parts of silver. It must not be assumed that this is always the composition of the gold-toned image, as it must necessarily always be dependent upon the depth of toning. Mr. Bedford's work, as all are aware, is toned to a rich purple colour; consequently a much larger proportion of gold is reduced than would be the case with brown tones. In prints toned only to the red-brown stage, the proportion of gold must necessarily be very small.

THE composition of the platinum-toned image, as in Mr. Blanchard's process, can, of course, be accurately arrived at in a similar manner to that just referred to, and the larger the scale worked upon the more reliable and conclusive will be the result. Furthermore, in dealing with a large number of prints at a time a more correct general average is obtained.

On several occasions we have directed attention to the yellowing of gelatino-bromide pictures, the result of imperfect fixation. We once more recur to the subject, as we are frequently seeing fresh examples of this defect. It is scarcely necessary again to remind our readers that the deterioration is not due to the process, but to gross carelessness, or, perhaps, ignorance, on the part of those who do the work, though in the end the process itself may suffer in reputation. Many workers who are unacquainted with the chemistry of the subject imagine that when the visible bromide of silver disappears that the picture is

sufficiently fixed: no greater fallacy exists, for in this time the bromide is only converted into the hyposulphite of silver, and not the soluble double salt of hyposulphite of silver and soda, which alone can be removed by washing. The hyposulphite of silver is practically insoluble in water, and therefore remains in the picture to ultimately produce yellowness.

SOME time ago we published, on the authority of Dr. Vogel (whose communication appeared in *Anthony's Bulletin*), an account of a new lens by Herr Miethe, of Potsdam, which was thought to be calculated to almost revolutionise one's ideas concerning photographic lenses. On another page, and this time from the pen of Herr Miethe himself, we give a second instalment of its properties, from a perusal of which we are led to inquire whether there may not exist a similarity between the foreign production and that of Dr. Schroeder, of which we gave a drawing and description a few weeks back.

THE longest day of the year 1889 is past, and from this time the days will gradually shorten. Those amateurs whose principal work is confined to Saturday afternoons should now arrange their outings, so that the longest excursions are taken while the days are longest. Those districts which are situated nearest home may well be left for the shorter days. Frequently, societies which organize afternoon excursions use up the nearest localities when the days are at their longest, and, as a consequence, have to go farther afield as autumn approaches. Hence time which might be profitably expended in taking pictures is often spent in travelling, frequently to find, when the destination is reached, that the best of the light has departed.

LAST week we alluded to fire insurance and professional photographers. A hint may well be added with reference to those who follow the art as an amusement. Many amateurs have quite as much valuable apparatus, indeed, often more, than is possessed by some professionals, and for which, we venture to say, nothing could be recovered in the event of its destruction by fire. Although the owner's household furniture may be fully covered by insurance, photographic apparatus is not household furniture, and, according to the case quoted last week, the premium upon it is widely different. Therefore, those who may have a quantity of valuable apparatus will do well to act upon the hint, and either obtain a separate policy upon it or, at least, have it added to the existing one.

CORRESPONDENTS have been writing very frequently of late inquiring whether dry plates are made which are suitable for the production of positive pictures, like the glass positive of old or the ferrotype. This is a subject that might be worth the consideration of some of our plate makers. There is very little doubt, if good positive plates were put upon the market, that they would meet with a certain amount of commercial success.

GLASS positives in England were always looked upon as being somewhat plebeian, possibly from the low price at which they were produced in some quarters: yet there is no gainsaying the fact that a really good glass positive, such as some few photographers used to produce, is by no means to be despised. If it was the low price, as some assert, that killed the glass picture, it is to be hoped that paper ones will not share a similar fate. Fairly presentable *carte de visite* portraits are now to be had for half-a-crown a dozen, and we do not remember glass positives of similar dimensions being done so cheaply as this.

ON THINGS IN GENERAL.

THE remarks in a leading article in these pages upon Fire Insurance are well worthy of perusal by every one possessing an insurable interest in matters photographic. A policy holder is usually told in print to read his policy: a policy holder, as a matter of fact, does this in perhaps one case out of a hundred. It is astonishing with what *laissez aller* this most vitally important subject is treated by the majority of clever men of business even. How many know that

they are prohibited from employing workmen to alter premises, for example, without due notice that the presence of a lath and plaster partition between themselves and a neighbour with a risky business, if not declared, might lead to the claim being contested in the event of a fire from the neighbour? Above all, how many are aware of the common introduction of an "average clause?" This clause, sometimes gummied on the edge of a policy along the side, as I have seen it done, acts thus, "If the premises contain at the time of a fire a larger amount of goods than the policy covers, the insurer will only get a portion of the amount insured if the fire is not wholly destructive." Thus, if 500*l.* is insured for and the stock is 1000*l.*, then if, say, 400*l.* damage is done the insurer gets only 200*l.*, and so on. I advise every one who reads this to look at his policy, and object to renew it without the clause in question is expunged. With regard to the risks of photographers' premises, I was not long ago assured by a gentleman who held an important position in a Fire Insurance Company that the existing average rates now charged are not at all out of proportion to the risks. I am inclined to believe one cause to be the facility with which fires can be brought about by dishonest occupiers without leaving a trace behind of the means employed. Of course there still is danger where spirit or ether, or both, are employed. I have heard, for instance, of one photographer who has received compensation from insurance companies on six or seven different occasions, and has received considerable sums; he is very unfortunate, and the rest have to pay for it.

I usually read with interest Professor Stebbing's letters (he had a painful experience of how French insurance offices carry on their businesses) and therefore notice his description of M. Guilleminot's system of obtaining large images of distant objects without the use of a telescope. He uses a lens, say, of forty-five centimetres focus, and at its focus for a particular object places another of, say, five centimetres focus, and this latter enlarges the image to a great extent. Now I have to remark upon this that the same plan was described in this JOURNAL very many years ago with application to astronomical objects; next, to insure anything like a good amount of sharpness, picked lenses will be needed; and, lastly, that to expect to take a photograph of an object five hundred metres distant, and of the same size as that object, is simply ridiculous. There are the germs of real usefulness in this resuscitated plan, but for Mons. G. to make such extravagant claims is calculated to throw the whole plan into disrepute.

This rejuvenescence of old ideas seems to be quite in vogue at the present time. Thus, in the list of patents given in this JOURNAL on May 24 I find one for a method of mounting two prints, such as opposite sides of a document, back to back, without the intervention of a sheet of paper or card. Certainly twenty years ago, and, I believe, more, I saw a series of copies of letters of introduction from eminent men of science in this country to others in America photographed and pasted together in this manner by the gentleman who was to present them, and who adopted this plan either for safety or as advertisement I do not remember which.

Another patent described interested me very much, and was not open to the same charge. It was that of Messrs. Thorns, for rendering foul-smelling albumenised paper pure and sweet. It is to be a great boon to the unfortunate sensitizers who, as is too often the case, work in a confined space at this particular employment, and who rarely get used to the vile odour; but at the same time it is a question whether it would be wise to avail oneself of any such plan, seeing that the honest maker of pure paper would be handicapped by the producer of the nauseous kinds being able to introduce his inferior article as though of the same class.

Then again, June 7, we have a patent for binding the edges of magic lantern slides with thin brass instead of fragile paper. My first practical connexion with photography dates more than thirty years ago, and even then these brass bindings were in use. They were called "preservers," and were sold so much each. In a few years time the price per gross was not much greater than the unit price.

Many photographers will demur to the conclusions of Mr. V. C. Driffild as presented at the Liverpool amateurs' meeting the other day. He said, "It is popularly supposed that a great deal can be done in development to modify the effect of faulty exposure. Careful experiments made to decide the question, however, show that

this control during development is, to say the least of it, greatly exaggerated. A technically perfect negative can only be produced by a correct exposure." In the main I entirely agree with this dictum.

FREE LANCE.

ECHOES.

I THINK I have on a previous occasion commented on the—to use the mildest term—somewhat misleading impression created by the reports of society meetings as they appear in print. It is perhaps difficult, *in a hurry*, to condense into a small space the meaning or sense of a speaker who is not over-well able to express himself with brevity; but an apt *precis*-writer would never find a great amount of trouble in the matter. Diffuseness in reporting is no way out of the difficulty, nor would the publication of *verbatim* reports improve matters much, for I venture to think and to express the opinion openly that the so-called "*verbatim*" reports in the poor old "parent" JOURNAL—especially when improved and prepared for the press by the speakers themselves, under the existing system of submitting to them "proofs" of their speeches for correction—are among the most unintelligible of the published records of photography. It is generally difficult enough to carry away anything of an instructive nature from the Pall Mall meeting, but it is hopeless to expect to derive any valuable information from the official report.

But there are ways and ways of not expressing the sense of a question, a remark, or a speech, and sometimes the very obviousness of the intent of the speaker, while leading the reporter to only half record what was actually said, at the same time renders quite clear to the reader what has been the extent and character of the omission. I was led to commence these remarks by reading in a report of the North London Photographic Society that a member "asked what difference there is between bromide of potassium and bromide of ammonium." Now the only answer to the puzzle as it stands is, to put it in chemical terms, that one is KBr and the other NH₄Br; but I imagine this information would scarcely have satisfied the querist. If the report had said that the question was one of difference of action either generally or for a specific purpose, it would have been better. I judge from the context that the inquiry related to the difference of effect produced by the two salts when employed as restrainers in development, but the information elicited in reply was meagre, and, at the best, open to proof.

For instance, Mr. Valentine Blanchard is reported to have laid it down as an established fact that bromide of ammonium produces a yellow stain with hydroquinone, while bromide of potassium does not. Now, so far as I am aware, the only evidence in that direction consists of the published experience of Mr. Alexander Cowan, to the effect that under certain circumstances the yellow stain had been produced when bromide of ammonium was used, and not otherwise. But whether the effect was really due to NH₄Br, *as such*, requires, as I have already had occasion to suggest in previous "Echoes," absolute proof. Perhaps Mr. Blanchard—and this I think is most likely—merely mentioned Mr. Cowan's experiments and conclusions.

Professor Stebbing frequently gives us some amusing information from the meetings of the French Photographic Society, but his description of M. Guilleminot's method of photographing an object—a bird for instance—life size, at a distance of 600 yards, in an ordinary camera, is more than ordinarily entertaining. We are told of the difficulties surrounding the operation, when a "large telescope" has to be carried about for the purpose, but it strikes me that the alternative arrangement of a "simple camera," with its attachment, does not shine very conspicuously as an improvement so far as portability is concerned. For instance, we will say we wish to photograph the homely sparrow life size, for which purpose a half-plate would probably be large enough. Upon this camera we fix an eighteen-inch focus lens, and focus "as sharply as possible." I say nothing about the question as to whether the half-plate camera has a sufficient extension for the purpose. Some of them have, but I wonder how, with the "simple camera," mind, we are to replace the focussing glass by a second lens of about two inches focus, and enlarge up to "the life." Further, I greatly wonder what sort of definition would pervade the resulting picture.

I can quite agree with the Professor in thinking that a very con-

siderable amount of "noise and excitement" will be caused when it becomes known that "the portrait of a battery can be taken" (life size) "some miles away from the operator," but we have to arrive at that stage yet. It may be that the French are in advance of the Germans in military photography, if not in other respects.

Then, again, M. Thouroude's test for "safety" in red glass seems to me rather useful than scientific, that is, if it be reliable. After laying down the proposition that an ordinary spectroscope is of no use as a test, M. Thouroude goes on to say that if a piece of glass known to be "safe" is laid down upon an engraving side by side with a piece of the glass to be tested, and the colour and intensity of the lines are the same through both glasses, all is right. But if the lines appear paler or grey through the doubtful sample of glass it is to be condemned. It strikes me very forcibly that it must be a very bad sample of glass that would respond to this test, and a far worse spectroscope that would not reveal its badness!

The same gentleman, M. Thouroude, next exhibited a *new* hand camera, the invention of an amateur, by means of which "sixty shots could be got per minute." After reading the description, I can only conclude that the "novelty" consists in the claim of sixty exposures in a minute—that is new to me; but the camera was patented in this country six years ago, and has been constantly exhibited ever since. Whether the inventor is an amateur or not I do not know; the French "discoverer" of the ancient invention may be.

Adapters for lens flanges appear to be entirely unknown in France, or surely the cumbrous method "presented" at the same meeting by M. Molteni would scarcely have received serious attention. Fancy having to attach to the camera front a double disc of ebonite with an aperture large enough for the largest lens to be used, and then fitting each lens itself with an ebonite flange, the outer dimensions of which equal those of the largest lens! Fancy a portable symmetrical so "adapted" to fit a whole-plate portrait flange!

M. de Villecholle's method, which is stated to be simpler, is, I am sorry to say, quite unintelligible to me as described, so I cannot say anything either for or against it.

After reading Professor Morize's suggested plan for the detection of irradiation, or rather for proving that reflection from the back surface of the glass is the cause, or one of the causes, of distortion in stellar photographs, I cannot help wondering at the curious manner in which similar ideas crop up applied to very different purposes. Professor Morize's suggestion is to silver the back surface of the glass with the object of *eraggrating* the irradiation, and so making it recognisable as such. Just about fourteen years ago precisely the same method was proposed by Canon Beechey for *preventing* halation, and specimens to illustrate the success of his method are stated to have been left at the editorial office of the JOURNAL. Here is an illustration of "blowing hot and cold" with a vengeance.

But while Professor Morize's view of the probable result is undoubtedly the correct one, it does not follow that Canon Beechey's application of the same method for a diametrically opposite purpose is entirely without favourable result. I had the privilege of examining his specimens at the time they were made, and they certainly bore out his contention. But I think, speaking from memory, it was pointed out editorially at the time that the result was rather due to the minimising of reflected *diffused* light from the back of the glass than, as Canon Beechey seemed to think, to the rays being reflected back to strike the sensitive film at the same points through which they first passed. A glance at Professor Morize's diagrams will show the impossibility of that.

The description of the liquid prism, quoted from the *Scientific American*, in a leaderette last week reads very smoothly, and the whole operations involved in the construction seem perfectly easy. But I am afraid that nine out of ten of the readers of the "BRITISH" and of the *Scientific American*, who may attempt to follow out the instructions, will find matters not quite so straightforward as they look, and the final result, even when moderately successful, not such as to justify the trouble, at least where accurate results are required in photography. For mere demonstration purposes such a *cheap* prism may be easily made: but where extreme accuracy is necessary, the advantage of the built-up prism does not at all lie in the direction of economy, for, *ceteris paribus*, it becomes practically as expensive as a solid one. But where great dispersion or large size is necessary the

liquid prism is useful; but it must be very carefully constructed, and when constructed very carefully treated.

Mr. C. Brangwin Barnes is surely "playing to a rather low-class audience" in preaching the resurrection of the long-defunct "binary" pictures, once so called, as "good business." I am quite certain that no photographer of repute would adopt such "catch-penny" means of improving (?) his business, and if he did I am equally certain he would find the attempt a failure.

JUNUS.

A METROPOLITAN PHOTOGRAPHIC SHOW ROOM.

A FEW days ago we visited the new show rooms of Messrs. Marion & Co., the eminent photographic manufacturers and merchants, of Soho-square. It appears that the premises there, extensive as they are, have been found inadequate to the displaying, not of stock, but of even samples of stock. Nor is this to be wondered at when one considers the multifarious additions to the requirements of the photographer which, in this epoch of rapid and fertile invention, have to be made almost daily.

The new show rooms of this firm are situated in that portion of Rathbone-place, Oxford-street, so long sacred to art and its belongings, viz., large firms devoted to the supplying of artists' and painters' requirements. Indeed, the very premises in question as now occupied by the great Soho-square firm formed at one time the show rooms of the Autotype Company, in those days when it was in a large measure the property of, and was controlled by, the senior partner of Winsor & Newton.

Messrs. Marion have arranged their large display in an admirable manner. The counters are at such a distance apart as to permit of easy passage between them. The classification of goods is systematically effected, there being two or more articles of each kind placed contiguously, facilitating a thorough examination of any one class. Is it cameras? Well, on one bench is found arranged so many of all makes and sizes as well-nigh to induce a feeling of embarrassment from the plentitude and variety of the display, there being here every member of the camera family, from the mammoth down to the little pocket instrument.

This choice is assisted by the best of all guides—*i.e.*, comparison. The same holds good throughout in this show room. Here are samples of everything required for the dark room—for instance, a customer has the choice of ten or a dozen sorts of developing dishes, a large variety of lamps, and formulæ for development already made up for use; and for printing or finishing prints there are a large variety of burnishers and rolling presses, a variety of paper for all the different processes, and for backgrounds and accessories tables and chairs. The choice is large and varied. The customer can see the very thing he may want to purchase, and have the very article that he sees delivered to him.

In fact, everything a photographer may want he will find here sampled. If about to start a business he can see samples of all his possible requirements.

ON EXPOSURES.

[A Communication to the University College Photographic Society.]

IN introducing the subject chosen for this evening's discussion, namely, "Exposures," I shall confine the few remarks I am about to make to exposures in the use of the camera, leaving exposures in contact-printing, enlarging, &c., for other members to deal with. In this limited sense, then, what is meant by exposure is simply submitting a sensitive surface to the action of light thrown upon it by a lens, and emanating from or reflected by the object to be photographed, and this for a sufficiently long time to obtain a developable image. But a developed image is not all that we require; developed images vary very much in quality and character—we call one an under-exposed negative, and another an over-exposed negative. What we require is the best obtainable image or negative, and in obtaining this the beginner finds considerable difficulty. He finds it will not do to under expose or over expose, but that he must aim at "correct exposure." By this I mean an exposure which will give the best negative with a "normal developer."

I have somewhere seen it stated that the briefest possible impact of light (strong or weak) is sufficient to bring about that molecular

condition, which, on development, we find to obtain. If this be the case, it is to the developer that we are to look for the quality of the negative; that is to say, the developer must suit the exposure, and this is found to be the case to a certain extent, for we continually find it necessary to vary the developer when in the dark room—in one case keeping down the accelerator and increasing the proportion of the restrainer, and in another just the opposite. But we sometimes have plates to develop which have received perhaps a brief exposure, and with the developing agents we have, use them how we will, we cannot get a satisfactory negative, *i.e.*, we find that, in practice, there is such a thing as under exposure. What we have to aim at, then, is an exposure that can, by the ordinary reagents used, be developed into a good printing negative, in contradistinction to an interesting chemical effect.

Plates vary much in their sensitiveness and in their ability to withstand prolonged action of the developer (an unsafe light in the dark room may sometimes be the real culprit in the latter cases, consequently it is a good plan to adopt a well-known brand of plates, and to stick to that brand; the knowledge of the correct amount of exposure will then, after a little practice, come as a kind of instinct. Unfortunately, this does not always work to one's complete satisfaction, for in the same brand of plates the different batches sometimes vary, but to nothing like the extent they used to vary a few years ago.

If one works with several different lenses, one must get used to these, for the illuminating power of various lenses varies considerably. In judging the necessary exposure, one must take into consideration, not only the *quantity* of light on the focussing screen, but also the *quality* of that light. Don't focus with full aperture or a large stop, then insert a small stop and expose, without looking at the effect on the screen with the small stop in; if you do, you will be very liable to misjudge the amount of exposure necessary.

Having given a "correct exposure," how far shall we push the development? For my own part, I do not like a negative with absolutely clear glass in the deepest shadows, this may answer for a lantern slide, but a negative with a slight deposit in the shadows generally gives a better print. But the subject of development will be a very good one for some future discussion, and no doubt will soon receive attention from us.

To-night, we must confine ourselves more exclusively to "exposure," though, as I have pointed out, the two things hang together very much. We often see in the various photographic publications elaborate "exposure tables" drawn up, but as the light we have to deal with is a continually varying quantity, I do not see how these can be an unfailing guide to us, unless used with a perfect actinometer, and this I believe has still to be invented. But even with this we are still at the mercy of the varying sensitiveness of plates. With developer and plates constant, the latitude of exposure increases with the blackness of the shadow, because the darker the shadow in the object, the longer the exposure that can be given to the subject before the diffused light caused in the camera by reflection from the image of the highest lights causes reduction in the image of the shadow.

With subject and developer constant, the latitude seems generally to increase the slower the plate, for this reason, that a proportionate increase of light generally produces greater increase of density in a *slow* than in a *rapid* plate. Therefore, in still subjects, where length of exposure does not matter, the slower the plate the better, or the smaller will be the loss through wrong exposure. The more rapid the plates, the less the latitude of exposures. The greater the illumination of the shadows in proportion to the high lights, the less the latitude of exposure. Also, I may add (for I can't leave development out of it), the greater the amount of pyro or bromide, or both, in the developer, the greater the latitude of exposure; and the more ammonia, the less the latitude of exposure.

"Correct exposure," then, is to be ascertained by observation and experience. Make trial exposures, and let your plates be your actinometer. Tables are useless unless they deal with constant conditions and quantities. In exposing gelatine plates, the only constant is the aperture of the lens, and this we vary by introducing various stops, but here the variation is of known extent. The rapidity of plates, the character of the subject, the character of the light, the distance of the lens from the focussing screen, are all continually varying, as also the method of development used. How then are we to arrive at correct exposure? I can give no definite rules the following of which would always lead us to "correct exposure."

It seems to me that experience (alone) does it, and to gain this experience I would recommend the beginner, in the first place, to pay great attention to the effect on the focussing screen, with the stop to be used inserted every time he is going to expose a plate; also to provide himself with a book (for memory is treacherous) in which to note date, time of day, plate, lens, and aperture used,

condition of sky, exact composition of developer used, and the like. In this way he will soon acquire that *instinct* which alone tells us what exposure to give.

E. S. WADSWORTH.

PHOTOGRAPHIC USES OF URANIUM.

III.

Of a printing process in which metallic uranium was deposited to form the image there has not appeared to my notice during the last decade any description. I select this span of time, as it probably covers the period at about which, according to a remark on page 67 of this volume, the details of an uranium process there attributed to an esteemed worker might have been made public. I have not been able to find mention of such an adaptation of uranium, and am led to state so much for fear of being charged with treading a beaten track. If the latter is the case it will have been in pure innocence. Moreover, I do not remember reading in the published memoirs of the principal photographic experimentalists of the last thirty years any similar reference, although it is not improbable that allusion may have been made to the theoretical aspect of the subject.

Previously, when touching upon the reaction between ferrous oxalate formed by light from the higher or ferric compound and solution of uranic nitrate and gold chloride, the effect being a positive image chiefly of the first mentioned metal, I submitted the proposition that, although the protoxalate of iron appeared incapable of depositing the uranium without the presence of a small quantity of gold, over which it freely exercises the power named, it might, nevertheless, be found practicable to dispense with the assistance of the gold, and by means to be ascertained to effect deposition of uranium alone, and so secure an image wholly composed of that metal. Furthermore, I left the precise behaviour of the unchanged ferric salt towards the uranium in a state of doubt, as there seemed grounds as tenable for supposing that it was nugatory as for concluding that it was not inactive. I will now venture briefly to deal with these points.

A comparison of uranic nitrate with ferric oxalate as temporary image-forming agents has already been made, and the resemblance one to another of their properties duly noted. There is also a close likeness between the first-named substance and the platinum salt in applying one or the other to an iron image, as ferrous oxalate will not solely deposit either metal. This being understood, it is natural to argue that since the platinum may be thrown down by conjoining to the ferrous oxalate a developing agent such as potassium oxalate, the uranium salt is capable of being similarly influenced, and experiment proves the correctness of the deduction. If, therefore, a solution of ferric oxalate be brushed upon paper, and the latter dried in the dark and printed behind a negative, metallic uranium may be deposited upon the parts that have been affected by light by floating the picture upon a solution of uranic nitrate and potassium oxalate. At the same time, it will be remarked that the unexposed portions—the ferric oxalate—will not attack the uranium, but by the combined action of that and the potassium salt will be displaced from its support, leaving clear paper, and requiring nothing more than a final passage through plain water to remove minute deposits. Thus, setting aside the photographic qualifications of the method, which are not, in the present regard, of first consideration, the effect of the reaction between these three bodies is to confirm the proposition that the metal uranium may be deposited to form the image of a positive impression upon paper.

In the attempts made to determine the exact quantities and proportions of the uranium and potassium salts necessary to insure the proper depth, some not uninteresting experiences were met with. Occasionally the deposit would be coarse and granular; at other times one might conclude, from the perfectly homogeneous appearance of the picture, that the uranium was very finely subdivided. Extensive variation in the colour of the several deposits was to be noticed, coarseness being coincident with brown blacks. The prevailing appearances of the uranium image are entirely dissimilar to those in platinum and silver, and do not easily admit of written description, but I think they are sufficiently pleasing to support the belief that a perfected uranium process would be capable of yielding pictures having quite distinctive features, and perhaps possessing value as a photographic printing method.

Although meeting with success in the endeavour to obtain an uranium positive image, it is the bare truth to admit that so far as I have proceeded the quality and strength of this kind of picture is not fairly comparable to that which may be had by making to the uranium solution an addition of a little gold, which, while largely assisting in the effective reduction of the uranium, imparts depth to the image and a pleasing moderation of the colour to heavy purple black. Still, I fancy that if the exact quantities of uranic and developing salts can

be ascertained, and various other details decided—a matter of some difficulty, of course—the nature of the results would justify the absence of gold or other coadjutants.

I prefer to avoid the large questions of the stability or permanency of deposited uranium on paper, but before quitting the subject it is permissible to suggest another way in which the properties of the uranium salt might be utilised, namely, in its conjunction with either ammonia- or sodium-ferric-oxalate, and its application to a support, when, as in the parallel instance of a platinum process now in vogue, its probable reduction and development, under the influence of light and moisture in the printing frame, might lead to the provision of a highly simple method of obtaining uranium pictures. The fact that the principal reducing agent, the iron, and the substance to be reduced, the uranium, are both sensitive to light points to the inference that great rapidity would characterise such a process if it were found practicable.

THOMAS BEDDING.

THE EMPLOYMENT OF THE OPTICAL GLASSES RECENTLY MANUFACTURED IN JENA FOR PHOTOGRAPHIC LENSES.

As is generally known, an undertaking has within the last few years been set on foot in Jena under the direction of Professor Abbé, which has for its object the scientific manufacture of optical glasses with regard to the advancement of practical optics.

The chief object to be attained was the removal or diminution of the secondary colour aberration; at the same time, the successful attempt was made to vary the optical qualities of the glass fluids by introducing into them new elements. The relation between the refraction index and the dispersion, which previously in almost all cases had been a linear function of the first constant, was principally kept in mind, and glasses were produced which showed with almost the same refraction index very different dispersions. By this means it is possible to correct spherical aberration in the construction of telescopic and microscopic objectives, in large measure independently by chromatic errors, and in general to satisfy one more condition than formerly in the construction of optical lenses.

It is evident that great advantage may be taken of this fact in the case of photographic lenses, and I have endeavoured to follow this out mathematically. I had first to decide what new condition needed most carefully to be fulfilled. The secondary spectrum and the remains of spherical aberration on the axis seemed to me to require no more correction than the distortion of the field, therefore I made the attempt to fulfil a wholly new and hitherto only occasionally mentioned condition—the diminution of the astigmatism of the heteronomic pencils.

Astigmatism Heteronomic.—It is well known that the diminution in sharpness from the middle of the picture towards the edges is essentially due to astigmatism, and this defect has heretofore been supposed to be irremediable. I will not describe the process—more tedious than difficult—by which I found the analytical conditions of astigmatism. Suffice to say that I succeeded in thoroughly removing the serious defect by the use of suitable glasses, and in giving the formula of an objective which, resembling a symmetrical lens, is wholly anastigmatic.

Anastigmatic Distortion.—Apart from the last traces of distortion which cannot be removed, the lens—as was to be expected—showed the edge and centre of the field with equal sharpness, even with full aperture. I may also add, that in the case of the new lenses the flint has a smaller index of refraction than the crown, and that the lenses have the merit of being especially thin—a fact which secures an unusually great rapidity.

Two forms of lenses have been up to now made according to this method. The first is a symmetrical lens of $\frac{1}{65}$ equivalent aperture, which gives a correct image of 50° without a diaphragm, and with the smallest stop a field of 90° . These lenses are specially adapted for portraits, groups, and instantaneous work, and can be used with great advantage in detective cameras, where rapidity and sharpness at the edges of the field are necessary. In this respect they are vastly superior to all other forms of lens. A lens of three inches focus covers a plate $2\frac{1}{2} \times 3$ inches.

The second form consists of a simple landscape lens. It has an equivalent aperture of one-thirteenth, and gives, when sufficiently stopped down, a sharply defined field of 100° . This construction is particularly suitable for landscapes, and works very clearly and sharply.

So far both forms have been manufactured only in small dimensions and focal lengths, since the production and melting of suitable crown glasses of more than two inches diameter have been attended with

difficulties. It is to be hoped, however, that these difficulties will be removed and instruments be produced of any desired dimension.

The largest symmetrical lenses have a diameter of two inches, and a focal length of 6.5 inches, and work a plate of 5 x 7 inches. The largest rectilinear landscape lenses have fourteen inches focal length and work a plate of thirty inches; they are thus adapted in landscapes for the largest plates.

"*Anastigmat*."—It may be added that the symmetrical lenses which have received the name "*Anastigmat*" are not essentially dearer than ordinary glasses of equal size, while the landscape lenses are very cheap.

Hartnack.—The optical manufactory of Professor Dr. Hartnack, in Potsdam, 309, Waisenstrasse, has undertaken the construction and delivery of the new lenses.

A. MIETHE.

—*Anthony's International Annual*.

COPYING PAINTINGS AND WORKS OF ART.

III.—IN THE STUDIO.

SUFFICIENT has been said in the previous articles to show how old pictures may be treated, but one practical note more may be added to show how pictures, if painted on canvas, can be made to have the best appearance photographically. If the stretcher on which all cloth pictures are strained be a keyed one—i.e., one made with wedges for distending it—these should be lightly driven up with a hammer until the canvas is strained, but not unduly; and while doing this, or before doing so, all the dust and dirt which invariably accumulates between picture and strainer should be carefully removed. (I took a two and a half inch nail out of this receptacle last week from a valuable picture by Claude Lorraine.) If the strainer should be found, as many of the old stretchers are, and modern ones as well, to be made without keys, then a very slight damping of the cloth generally causes the picture to become tauter on the strainer, caused generally by two facts. The cloth is generally prepared with a coat of size or glue to smooth the surface before the preparing priming is used to prevent this from passing through, and this being damped along with the cloth, which shrinks in damping, the size shrinking and drying along with it tightens the picture on the straining frame without doing much, if any, injury to the picture.

Pictures which have not been so prepared are not so amenable to this treatment, and many painters of the highest repute have had the strongest objection to use the ordinary prepared cloth, preferring to have this preparation done on the cloth directly and under their own personal supervision, without the use of size or glue. When I mention the late Sir John Watson Gordon, President of the Royal Scottish Academy, as one, and Norman Macbeth, R.S.A., who was also President of the Edinburgh Photographic Society, as another, who practised this method of preparing their grounds, I will have said enough on that subject.

In reference to the studio itself, no matter what may be thought of it for portraiture, there cannot be a doubt that the "tunnel" shape, as it was called, suggested by Mr. Sutton in the "*Notes*" many years ago, is, for copying pictures and works of art, the best form that has yet been devised, having qualities of its own for lighting up the work that no other that I have used attains to, while it is as suitable for the use of all artificial illuminants as any other.

With ordinary light this form of studio gives a very equal illumination of the subject if it be a picture; but this is not its highest recommendation for copying of paintings, plans, and other works of a like nature, for the light passing to the object at pretty nearly equal angles all reflections are destroyed, and with the assistance of a black cloth of an absorbent quality spread on the floor, the camera and lens in the dark shade of the tunnel sees nothing but the subject of the picture. One precaution is invariably taken, however, and that is to place the head in front of and in contact with the lens, and if the picture does not show truly dead, then it is so altered in or out, upwards or down, on the easel until it is absolutely right; if it is not then truly parallel, which it must be, the necessary adjustments are made on the camera with its slide, which swings in all directions. With the judicious use of the blinds, the most perfect light and shade can be got, not only on pictures, but on statuary or other objects in the round or high or low relief. There is a command in the worker's hand of everything—from perfect light to perfect shadow—such as is seldom got in any other form of studio; and there are few forms which I have not tried and done fair work in.

In copying oil or water-colour pictures for engraving, photogravure, or other reproductive process, there are to the ordinary operator or amateur a great many new and difficult problems to be faced, that of knowing

and feeling the artistic handling of the work being of the first necessity in the reproduction, there being great differences in the style and character of the painting, which must be kept up and represented truly in the copy—one artist's work being solid and vigorous, another's being refined even to the verge of weak prettiness. These various effects of the artist's manner to be conveyed in another medium must never be overlooked, but carefully studied and reproduced for in a true or perfect copy. It is not alone the mere drawing which must be rendered into black and white, but the entire character and artistic quality and feeling of the work which has to be translated.

These remarks apply quite as closely to the reproduction of photographs by the gravure or any of the other process methods as they have been called; it is the spirit of the work as well as its mere *mechanique* which should guide in making the negative for reproduction.

In carrying out this idea every one must use his own judgment, but it will be found that the best results have always been got by long and full exposures. In the collodion days—which, by-the-by, for this purpose have not yet departed, work being produced by that medium which the gelatine has not yet approached—in the collodion days, as stated, these exposures sometimes extended in time to what many now will consider fabulous, occasionally amounting to between three and four hours, and the subjects not then over exposed.

The collodion and baths were specially made for the purpose, being heavily salted with deliquescent bromide and chloride in addition to the iodide, and the resulting negatives up to thirty-six inches high being without a flaw or a stain. With peculiarly difficult subjects, the interposition of colour screens was often resorted to with considerable success, but at that period they had not yet acquired their present names, and there is much in a name. The results, however, were similar.

In exposing then and now for such large plates experience has led to having the camera removed as much as possible from all vibration. In the present writer's experience this has been most successfully accomplished by having a suitable camera stand suspended from the roof of the studio, the camera sliding on rails and having all the necessary adjustments on both camera and stand. On a ground floor, of course, there would be no such precaution required, but in copying, especially for engraving and such-like methods of reproduction, no effort should be spared, or that foresight can effect, to secure rigidity, rectangularity, and absolute sharpness to the extreme corners of the picture.

This, it need hardly be mentioned, can only be got by using a lens which will fully cover the entire field. No amount of trying to make it do will ever satisfy the requirements, they must be there.

Much, of course, could be said about the ways of securing rectangularity in the copy, but that may safely be left to the practice of the worker, most people knowing that if the lens is placed in the middle of the camera and pointed to the centre of the picture—truly levelled—that a very slight but careful measurement from corner to corner of object and camera will insure that portion of the truth of the copy; but as this has extended sufficiently far already, anything further that may be actually necessary will be stated in the next and concluding article.

W. H. DAVIES.

JACK AND I IN NORWAY.

No. II.—BERGEN AND SURROUNDINGS.

WHEN on his first visit to Norway Jack had put up at the "Bergen" hotel when in Bergen, and on that occasion was very comfortable, so we decided to put up at the same house on our present visit. A good house and a very heavy landlady; had she possessed her weight in gold, she would have had over twenty stones of it.

Having seen to our baggage, that it was carefully stowed away, we started to photograph at once. The weather was beautiful, and if general report is to be believed, that is an exceptional thing for Bergen, which is credited with continuous rain. It is stated that every girl in the place is presented with an umbrella when she is born, as a thing quite indispensable to her future well-being. We saw them faithfully carrying about these "*Sarah Gamps*" everywhere, but they proved more ornamental than useful during the time that we were in the city.

Arranging our apparatus, we started picture taking, but had got scarcely ten yards from the hotel door when we were accosted by a young good-looking fellow, who exclaimed, when he saw our traps, "Oh, you are going to photograph! Then you should have come to our house," pointing to another hotel exactly opposite the "Bergen." "It is the best house in the town for photography. We have a flat roof on top—splendid for views. Won't you come?" We explained to him that we were staying at the "Bergen." "But you might come when you return again," he said. And replying that we might do so, he went away quite pleased. That's what I call looking after business. "*Smebys*" was the name of the

house, and the lady and gentleman who were going on the tricycling tour had put up at it, and they told us after that it was a very comfortable place. To those who desired panoramic views of the town that house might be an advantage. I have never found pictures taken from house-tops or church steeples very satisfactory or effective—all ridges, roofs, and little else, as a rule.

The principal street stretched from end to end of the business part of the town, the intersecting streets to the left inclined down to the harbour, at the bottom of which were jetties built out for loading and unloading boats and larger vessels. The quaint formation of these narrow side streets and the towering buildings—all of wood, mended and patched over—produced subjects of peculiar interest to photographers, artistic bits peeping out at every corner. There was no lack of subjects, and we wasted no time in starting to make pictures while the sun shone.

We worked all open subjects with a Ross' rapid symmetrical 10 x 8, so that the whole plate got well covered to the edges with a large stop, but in confined situations this lens was useless. We had with us for such emergencies a set of wide-angle lenses, respectively five-inch, seven-inch, and ten-inch focus, all fitting into the same tube. This was all we required for taking buildings, churches, and like subjects situated at very near distances. To get some of the most interesting subjects in Bergen we found this little set of lenses quite indispensable to us.

The crowds that gathered round when we were arranging and focussing for exposure were enormous, but very quiet and orderly. The policemen were the most polite of officials. With some little force and steady perseverance they pressed the crowd back beyond the angle of view, and with this kindly assistance we got some pictures that it would have been impossible to get otherwise.

Our tricycle friends had taken advantage of the propitious weather, and we came across them at different points as busy as ourselves. Jack put them up to a rather good dodge at one place where they were rather bothered with the crowd. He got them to focus the view they really wanted quite sharp, then turned the camera right round, pretending to be very busy taking a picture the other way. Naturally the crowd veered round right in front of the lens, then the camera was turned back to the view wanted and the exposure made. This was done successfully, and the crowd looking on from the back.

The shipping, the harbour, the market-place, and the new park and its surroundings were the spots that took up most of our time. The narrow short streets running from the main thoroughfare to the bay being the most picturesque subjects of any.

We took a picture of the market-place where the fish is sold, and a very animated scene it was, where the crowd of housewives came to badger the crowd of fish sellers. There was the same amount of talking, and wrangling, and priggish down, and chattering that is to be found in like circumstances all over the world I suppose. Lots of fish here are to be found swimming in tubs and other receptacles, so that you can buy them all alive and carry them away after their *quies*.

There is no covering to this market-place; it is an open square space close to a quay, the vendors selling from deal tables and other temporary erections of the commonest description; also the boats at the jetty run in close to the stairs, and sell the fish from their boats just as they have brought them from the sea. Here and there in the crowd would be found a stall of very questionable sweets, and others of hardware and small wares of a very common order.

In the main thoroughfare of the town the shops are good, and in most cases the articles are beautifully displayed. The general class of merchandise shown is naturally that which would commend itself to the tourists who must, during the season, visit Bergen by the thousand. Silver jewellery shops are a feature of the place—large windows filled with silver, and silver and gold ornaments in wire and filagree work, brooches, bracelets, bangles, ear-drops, and all kinds of ornaments likely to commend themselves to the ladies. These little articles are exposed in thousands and thousands, and this very display proves that there must be a large manufacture, and the large number of people who trade in it would convey that it is a profitable business.

In very old silver also, such as would delight the hearts of collectors (if genuine), there are large quantities shown, but this trade is done in a different way, usually a shabby case at the entrance to a narrow lane, with some six or eight pieces tacked on to the back of the case, which is glazed, and hanging on the wall. Apostles' spoons, old rings, ladies, &c., with a rather worn and dirty business card, giving the name and address of vendor residing in the lane, everything in keeping—very old and very dusty; but it repeated itself so often at different corners that I began to doubt if it were genuine or only a manufacture like the rest. It put me in remembrance of the artist, who, seeing an old suit of mail of the fifteenth century exposed for sale at the door of a curiosity dealer in Paris, was attracted by it, and inquired the price. When that was stated he said he would buy it now. "Oh, we cannot sell you that one," said the Jew in attendance. "I have just sold it this morning; but," and with the blandest and most innocent of smiles he continued, "I will have another one ready for you in three weeks if you like." The artist couldn't wait. So that, as I looked at these very venerable pieces of silver plate, I wondered if the stains and wear of age were all put on to deceive the unwary.

The next emporium of importance is the fur warehouse; then the general fancy ware and toy shops. White carved wood in spoons and

forks, figures, &c., are also manufactured here. Most of the goods shown are manufactured, or represent in some way the produce or peculiarities of the country got up specially to tempt the stranger. And, judging by ourselves, they are rather successful in their temptation.

The better class of people here dress much as we do ourselves, but when we come down to the workman or the peasant (who seems to be always trudging or sailing out and in to town) their get up is very unpretentious and home made. The men look hard-headed, steady, slow-but-sure sort of specimens; but when you come to their clothing it is huge and unshapely, fitting the body evidently never having been thought of, hanging in straight lines all round the figure like clothes from pegs. The women are of a plump, low-of-stature, quiet, simple type, uniformly dressed in a rough woollen material, kill-pleated or quite plain short skirts, with a little dark shoulder shawl, coloured stockings, and heavy shoes.

The women, however, who come into town from the surrounding districts look resplendent in their varied costumes of red and yellow and gold, the tight-fitting bodice and fancy head-gear looking extremely smart; and the children, decked out exactly like the matrons, look pocket editions of the same. The women, when they come in from the country, invariably carry a small oblong box or trunk, painted in colours gorgeous as their many-coloured dresses, so that it is very noticeable. It seems that they bring the eggs, butter, and any other produce from their small farms in this *Gladstone bag* of a previous age, and carry back in it the necessities required for home.

When in Bergen I observed one performance that was peculiar but cleanly. On Saturdays all the shop people combine to clean the streets. Each tenant cleans his place right to the centre of the street in front of his own door, so that, each doing his own part, the town is left spick and span for the Sunday at any rate.

MARK OUTE.

THE DISCOVERY OF THE DAGUERREOTYPE PROCESS.

[A Communication to the Society of Amateur Photographers of New York.]

I AM conscious of my own unworthiness for the honour you have conferred upon me at this important occasion, knowing of others that have a superior claim for this distinction—those that have given the subject more careful study and would be better qualified to address you this evening; and it is to be hoped that we may hear from others on this subject. I am sensible of the greatness of the field, and, that others may have an opportunity to address you, my remarks must necessarily be slight and imperfect. I hope you will understand my position, and I will trust to you for an equitable consideration. Mankind little reflect what a privilege we enjoy living in the nineteenth century, for included in this are all the great discoveries. Truly this is the age of progress and invention. We are better prepared to-day to accept the announcement of any great discovery, and to look upon it with less incredulity, to encourage, and possibly capitalise it, than were the people when the announcement was made of actually impressing the image so often seen in the camera obscura, and producing in all its detail the reflected image, and making a permanent impression upon a sensitive surface. This paved the way for other discoveries, and to-day we have many important inventions that contribute to our welfare and happiness.

We have the best and cheapest farm implements, fire engines, firearms, fastest steamers and best railroads, telegraph, photography, anaesthesia, sewing machines, electric light, telephone, phonograph, and, last, flexible films. If any nation during the same time has done more, or as much, the fact is not generally known.

We are assembled here to-night to celebrate the fiftieth year of one of these many inventions, the greatest of all discoveries—photography, and to pay homage to the illustrious names of Niepce, Daguerre, and Talbot, not forgetting our own countryman, Dr. Draper. The name of each is associated with precisely that which he accomplished—names that will for ever shine forth as fixed planets in the shrine of invention. They will be everlasting on the tablets of memory, monuments in themselves, the best that can be erected to everlasting fame, and will never cease to be heralded to all the world. We need not write the history of these great men; it is too well known, for their noble gifts to science will ever share the same position that follows with their fame, and to-day we reap the golden harvest of their genius and invention.

You may wonder why I have added the name of Dr. Draper to the list. My reason in so doing is because Daguerre never succeeded in taking likenesses; when the French government purchased his process it was only adapted to statuary and architecture. The first successful Daguerreotype portraits were made in the New York University, 1840, by Dr. Draper, who overcame the optical difficulty which had defeated all the previous attempts. When the news of the discovery reached Europe, it was ascribed to the peculiar brilliancy of the American sun; but this theory was hard to reconcile with the success which attended the American artists, who soon prosecuted the business in London and Paris. Opinions may differ as to the real date of this important celebration; whether it should be chosen from the date of the discovery or the public announcement before the Chamber of Deputies by M. Arago, are matters of minor importance. Each progressive step in photography is worthy of special recognition, and it is to be hoped that steps will be taken to celebrate the occasion of that important date upon which M. Arago read the paper before

the French Academy of Science. The ultimate movement in all cases establishes the fact that this is the most wonderful invention of the nineteenth century, and it reflects great credit upon the Society in taking the initial steps to make this year one of celebration and commemoration to these great discoveries.

On January 31, 1839, the results of Daguerre's labours came forth fully finished for use. To France alone for the Daguerreotype is all honour due, and the liberality with which it was purchased and given for the benefit of universal science will secure to France the gratitude of all nations. This wise and generous step was at the suggestion of her most eminent philosopher, M. Arago, to whom Daguerre had confided the secret of his art. Struck with the splendour of the discovery, and foreseeing the advantages which science and art would receive from its application, he induced the French government to offer an unusual pension of six thousand francs to Daguerre, and to Niepce a pension of four thousand francs, for surrendering to the public the use of their inventions. When the secret was made known and the pensions granted, the seals which retained the secret were broken and the Daguerreotype became the property of the world. The genius of men like this comes like an incantation of science, and descends upon the world but once in a series of years, and the peculiar assemblage of faculties requisite to produce these wonderful results are seldom found together, each possessing that persistent will, and all claiming to share in the great discovery; some giving the result of their labours to science, others pensioned by a government, and to one must be added the desire for a patent granted by the English laws. This does not detract from their fame. They have accomplished enough to crown them all founders of our beautiful art. And while the invention has afforded employment to thousands, it may be safely said that it has given to art the greatest stimulus it has received in modern times. The colours of genius are determined by the ray incident on the first prism, and the light once decomposed by refraction no further refraction can again decompose. It is thus with photography, for to-day it remains the same incident ray (the camera lens and silver salts are in principle the same that were used by the early investigators), and no further change has taken place, and it is doubtful if any ever will. Many topics are important enough to deserve a separate consideration. All that can be alluded to in this short space of time will be to point out objects best deserving our attention; while, if time permitted, we could present a diorama of men all more or less connected with this history. To mention a few of the many may not be out of place—Niepce, Daguerre, Talbot, Draper, Fyfe, Claudet, Tizeau, Biot, Arago, Hunt, Ponton, Lassargne, Netts, Herschel, Moser, and Lerebours.

Horace Vernet, and Goupil made Daguerreotypes in Spain; Friedrichstal travelled in Central America for the Prussian Government; Davidson made first camera (optician of Edinburgh); Adamson first made pictures in New York.

If time were at my disposal, I should like to inquire into the various benefits that result from photography, and to show that it has had as great an effect upon civilisation as the telegraph, telephone, and steam engine. It stands alone, occupying a distinct position, and furnishing to mankind a new vision that can penetrate into distance or the past, a retina as faithful as the human eye, but whose impressions do not perish with the wave of light that gave them birth. It has had a birth and a growth among the people; it has, like many other discoveries, been singularly successful in interpreting the wants of the day and serving popular welfare. The noble works of the great masters are no longer the exclusive property of a single individual; they are now reproduced by the aid of photography and given to the world or published for the benefit of society. The whole world is brought to our view by the aid of photography, and to-day we find it occupying an important position in science, art, and all industries. To me it has always been a pleasure to look over the history of these great men, and to ramble through the literature of the important event has offered many pleasant hours of study. To-night I yield the field to others, for my mission is rather to describe the process than to describe the men. I

am inclined to think that I shall best meet your wishes if, instead of dwelling on the history of these great men, we include them all in one great class of inventors and benefactors to mankind, and in as brief a manner as possible outline the Daguerreotype process and describe the use of the apparatus that has been loaned from the photographic collection of the School of Mines Museum.

[Professor Laudy here went through the operation of buffing a silvered plate; then illustrated the use of the iodine sensitising box, and the funnel-shaped mercury developing bath. He also showed several old specimen Daguerreotypes.]

The Daguerreotype process is wonderful for its extreme simplicity, and when once explained it seems strange that it was not thought of before. The crowning wonder of all is that it was made at a time when materials were not only difficult to procure but far from being pure. Iodine was discovered in 1812 by Courtois, and bromine by Ballard in 1826. Little did they dream that their discoveries would lay the foundation of the science of photography, and it is surprising to think that no other compounds have ever been used with success, and it is not likely that others will.

L. H. LAUDY.

FIGURES IN LANDSCAPES AND GENRE.*

II. It is very hard to give any really simple definitions, of Vulgarly, for it is one of those things of which it has been said, "I know perfectly well what it means, so long as you do not ask me to define it." If you

press me, I cannot think of any better definition than a base and material ideal, and to that I might add, mostly due to ignorance or sloth. Mr. Quiller is not polite, but he goes to the point when he says Mr. Frith paints life as if it were a Sunday-school treat. Vulgarly and its antidote can only be so generally and vaguely described that it is hard to get any practical good from the description. Here, moreover, it is hardly necessary for me to caution you against the grosser forms of vulgarity, and the distinctions thus become all the more fine-drawn, diverse, and theoretical. The general remedy prescribed by Mr. Matthew Arnold for his vulgarised middle-class Philistines was culture, the knowledge of the best that had been thought and said. In art, at any rate, this prescription will be very effectual, if we take it in the form of knowledge of the best that has been painted and drawn and carved. I forget who the great modern painter is who always keeps in his studio a fragment of Greek sculpture. "When I am in doubt about any of my work, I always try it beside this, and if it will not go with this I know it is wrong."

Any one who has studied Classic Art and the Old Masters, and has taken the lesson to art, is not likely to be vulgar, into whatever faults he may fall. The study may not be of much direct use to him, except in draperies, but it cannot fail indirectly to influence his style, as Mr. Lambert showed in his excellent lecture on Phidias. Of course, it is very possible to be pedantic, and priggish, and dull, and unpractical, but there is a vital principle at stake; the right and the wrong are worlds apart, and you can see the distance in a moment by two examples, each the best of its kind. You remember Focardi's statues at the Italian Exhibition—*You Dirty Boy!* and the two street Arabs selling newspapers, *I was First, Sir!* Take those gamins, place them beside the Parthenon frieze, and gauge your taste by the result.

Unfortunately our remedy of drawing fresh inspirations from the old masterpieces rather fails us as one large and wholesome source of pleasure. The ancients are of very little account in Humour, and healthy laughter is rather apt to be improved out of the world by modern culture. Greek wit is to us in its original form, with one exception, deplorable stuff; perhaps it is that jokes require re-entring for each generation. And now in these days from laughing at Leech we have come to smile at Du Maurier, and probably our ultra-refined grandsons will read their *Punch* with muscles and sense of humour unmoved. The most vigorous humour of to-day proceeds from America, and not from—well, not from Boston. Such hearty laughter as is felt proceeds too often from the strongholds of vulgarity, and if that were to have the monopoly of laughter, I fear the future would belong to it. But surely that is not necessary; there is plenty of good fun in art which is not vulgar. Mr. Charles Keene, Mr. Harry Furniss, and the late Randolph Caldecott, all within the last few years, have caused laughter neither faint nor unworthy.

To take a single instance among photographs. Mr. Sutcliffe's variously-named picture of "Excitement"—the rear view of boys looking over a wall. That is admirable art, very good fun, and excellent taste. The limits must in each case be found by individual refinement, and I can think of no single definite restriction other than that of sympathy: no joke should ever be an undeserved scoff. Focardi in a durable statue degrades humanity into apedom, and asks us to admire the cleverness displayed. There is not a particle of love or tenderness in it, and I do not believe that any man ever did great work without love in his heart.

Before I leave Vulgarly, there are just two points which I would like to mention.

The first is to protest against the humorous misapplication of quotations, debasing the poetical currency, to adapt a phrase from George Eliot. A burlesque of a paltry thing may reveal its worthlessness, but to ridicule what is really noble or beautiful, so as to depreciate its worth, is an outrage. There is a great temptation to raise a laugh in order to enliven an exhibition, and I am far from saying that there are no exceptions. Let us only be sure about each instance. There is nothing to be gained by pretending that everything is sacred, but even that humbug is better than holding nothing as unfit for jest.

In the second place, of animals I shall have more to say by-and-by; here I would only protest against treating them in a vulgar spirit, for they have a character, a dignity, and a nature of their own. Landseer was a great animal painter, but his failing lay on the side of investing animals with too human an expression; in Ruskin's words, "Looking for sentiment or jest primarily, and reaching both by a feebly romantic taint of fallacy" (Mod. P., v. 263). As often happens, his shortcomings are more easily imitated than his merits, and that ultra humanising and degradation of animals are to be condemned which reach, I hope, the lowest depth in publishing a photograph of a dog with a pipe in his mouth or a cat in an old maid's cap.

III. Now, after these strictures on Unreality and Vulgarly, it may be asked, What are we to do, then, to make pictures by photography?

As I have said, my whole aim is to cry up originality, and to put down thoughtless and uneducated work. Now that I have explained these prohibitions of mine, I had much rather insist on their positive side, and couch them in an affirmative form—Be Real and Be Refined. To these I will now add a third—Be Expressive.

The more we use the camera, not merely to record whatever is in the way where it happens to be set up, but to work out and give embodiment to an idea, or to render some chosen incident or phase of life, the more

* Continued from page 415.

art shall we get from it. By selection and adaptation the mind of the photographer is visibly expressed, and in this personal utterance alone lie the springs of interest and vigour in art. Therefore, to cultivate our power of expression, to be able first to make up a story and then to depict it intelligibly, is the best way of developing the artistic capabilities of photography.

It is true that this story telling is a born gift, but it generally exists in germ, and may be developed by practice and cultivation. In the right surroundings a very slight incident will go far, and the true artist, who always has his eyes open, is not above helping his memory by a notebook.

A pennyworth of example is worth a pound of precept. I will not refer you to any photographs, or distress the modesty of some here, whose names I might mention, and whose blanches I should raise, but I will take the painter, Frederick Walker, as the best and most immediately profitable example. He died, you know, quite young, to the great loss of English art, before he was enough at home in oil painting to allow his fancy free scope, so that for our purposes I would refer you more especially to his water colours. Here is a photographure of his picture of geese at Cookham: it is a liberal education in figure treatment. There are more figures in it than a photographer could well introduce, at any rate in one exposure, but there is not one which is not full of life and suggestion. I can only fall back on quotation, and in the words of an eulogy, which was perhaps misprinted by one of our most esteemed journals, declare that "it makes a picture to water the teeth of any photographer." Look at the man on the left carrying the oar which makes so useful a line, and telling of the river close by, calls up such a host of fancies and associations: the other man, again, probably a keeper from the Hall, sent on a message, puts his head in at the door for a gossip, but cannot stay; and, above all, observe the perfect family group on our right—the infant poised on the mother's arm, while she talks to some one out of sight, and the two children, the younger losing interest first and beginning to play, while the elder, throwing back her hair, still listens to the talk. These are all mere accessories to the main subject—the girl and the geese—and only in the elder child is the face seen at all; in the others the expression is produced simply by gesture. Take all these figures in, and then turn and consider what the picture would have lost if they had been omitted and the girl had driven her geese through a village lifeless and deserted, as if stricken by the plague.

Walker's chief fault was over idealising his young ploughmen and snows into Greek gods, but that danger need not frighten you: it will be well if the camera does not exaggerate the clumsiness and heaviness of the rustic. But in story telling I think he is pre-eminent; for that reason I have begun with him as an example. Among the old masters Caraccio had much the same gift, but unfortunately his work is hardly to be seen out of Venice, and I dare say you would prefer something more recent. Hogarth, of course, is full of such sketches of character, but he is rather too tremendous and too much in earnest for our easier and kinder art, and in pastorals it is really only in the latter half of this century that there has been realism enough to render these pictures serviceable to us even as suggestions. But in Randolph Caldecott, again, and many of our recent English illustrators, there are excellent examples, and easily accessible. These men did each bit of their work with love, as if they had tried what fresh and charming conception they could give to each detail of it without detracting from the effect of the whole.

No incident, if appropriate, can well be too slight. A child stopping behind its companions to tie a lace, a pair of old women meeting or parting, a waggon leaving a village with children a-swing at its tail; these and the like incidents will make all the difference to a photograph: people will care to dwell over it, and looking at albums will no longer be the last resort of the bored or tedious guest.

There is an excellent hint for finding figures which was given by an old artist to Constable; he remembered it and acted upon it all his life, and I will now repeat it to you: "Do not set about inventing figures in a landscape taken from nature; for you cannot remain an hour in any spot, however solitary, without the appearance of some living thing that will in all probability accord better with the scene and time of day than will any invention of your own."

When all the world is before us, suggestions are much less likely to occur than when we see the right man, woman, child, or animal in the right place; then it is easier to find for our subject the appropriate and becoming attitude and action.

There is also a lesson to learn from it, although it may be a hard saying to those who have little time to spare—that the first requisite for landscapes is to spend much time in the country, always observing and treasuring up for future use occurrences and phenomena as well as localities suitable for our work. To painters, of course, this is a truism, but I do not believe that landscape photographers study nature half enough. They know they can turn on the machine and take a landscape, and between whiles they neither open their eyes nor occupy their minds with what they have seen.

In story telling, however, it is evident that to evoke any human sympathy some human emotion, however faint, must be portrayed. And this brings me to my next point, that all emotions are not suitable for photography. For instance, there are griefs which are sacred against all art. And some subjects are too revolting or too harrowing for the painter's use.

But for photography the limits are even more narrow than for painting, and all strong emotions are unsuited to it, for the following reason. The painter can paint a picture from reminiscences of a scene which he has witnessed, using models for the purely mechanical part, and rendering the actual expression from memory, if not from imagination. The photographer, as I have insisted, can only photograph a subject actually present before him. If he were to photograph the originals in their sufferings, he would be a heartless and intruding brute; if he were to photograph the seen with models, so far as it failed, the result would be theatrical and empty—revolting to our humanity so far as it succeeded.

I have made these remarks here already on Mr. Bramley's Academy picture, *A Hopeless Dawn*, which I had already thought of in this connection before it was mentioned by Mr. Lake Price. There are numerous instances among Mr. Frank Holl's subject pictures now at Burlington House. His love of harrowing subjects was made a reproach to the painter; but conceive a photographer who should be accused of illustrating every sentence of the Burial Service!

Perhaps I might take the Coventry legend as a sort of example. If the purity of Godiva herself could have been photographed, I fear the photographer would have been a degree worse than Peeping Tom. (Would his lens have gone blind, or got a flare-spot, or what?) If we were now to photograph the sham Lady Godiva, I think we should deservedly get a vulgar picture, artistically, for our pains.

The rule may be laid down in relation to our sympathy. If we should be so carried away at the time as to be unable or unwilling to photograph the scene, then equally we ought not to reproduce it afterwards. Thus, soldiers under fire, when the war correspondent could give them no help, or a lifeboat putting out to sea, would be good subjects enough; a broken-hearted widow or a dog drowning would not.

How far the snap shots of detective cameras are decent, or how far they have the taint of the interviewer about them, I hardly like to say. I think that much depends on the extent and degree of publication. For instance, there was a photograph widely circulated of the Queen laughing, evidently an enlargement from a snap shot. I am not a believer in the divine right of kings, but that did seem to me to be taking an unfair advantage, and publishing a libel calculated to bring into contempt. There is just a touch of eavesdropping about it (I have a detective camera myself), but to overhear a thing and keep it oneself is very different from shouting out one's discoveries to the world at large.

Since writing these remarks I have seen the decision of Mr. Justice North, in Pollard *versus* The Photographic Company. Time will, I hope, show that this is good law; the analogy between photographs and letters which belong to the recipient, but may not be published without leave of the writer, who, nevertheless, has no property in them, seems to me to be, at any rate, very good natural justice. It is very doubtful, however, whether this principle could ever be strained to cover cases where the original photograph had not been taken for payment.

A cat may look at a king, and so may a detective camera; but I do not see why this natural right should entitle a photographer to publish ugly libels of an innocent individual, solely for the photographer's own profit or glory.

But to return to subjects taken with consent of the sitter, and the emotions which make good pictures. What about love making? Is that too tender, too intimate, altogether too sacred a process, so that to publish any even of its lighter passages, not to say the fraudulent version of flirtation, is a sin and a shame? That is too hard a problem for me; I will leave it to experts, merely noticing that, as a matter of fact, lovers have, time out of mind, been regarded as fair game—if you can catch them.

In photography, the actual exposure of the plate is so short, and it is so wise a precaution to take a second version, with very slight changes, that there is some danger of repetition. If both copies are of nearly equal merit, of course each might be exhibited in its turn. Most of us, too, are badly off enough for models, and these must be so very far superior to the ordinary model of the painters, that they are very hard to get; consequently, the same person has a tendency to appear in all our pictures. It is true that I never heard of such blind persistence in the same models as was shown by Cignani, a Bolognese painter in the seventeenth century. Sir W. Stirling Maxwell tells us that there are two pictures of his extant in the palace at Copenhagen, in each of which the same two models—a man and a woman—have been painted. The first picture represents Joseph and Potiphar's wife, the second the Rape of Lucrece.

But in getting models to express our ideas, the great obstacle, and one which increases proportionately to the definite aim and heightened interest of our effort, is self-consciousness. As soon as a sitter knows what you are doing, however willing she or he may be, on comes self-consciousness, and unless you can dodge it or banish it there is an end of all naturalness. It is, no doubt, mere nervousness, and some people have a dramatic power of putting it away and successfully assuming some desired expression at will. But these are rare birds indeed. Sometimes the attention may be diverted, but unluckily for our purposes one set attitude is generally required, and there can be no free movement or action, or assertion of power, such as generally dissipates stage fright. But to acquire by rule the art of being at one's ease is like learning liveliness by jumping over chairs.

GRAHAM BALFOUR, M.A.

(To be concluded.)

PHOTOGRAVURE PROCESSES.

[A Communication to the Society of Amateur Photographers of New York.]

In general terms all practical photographic methods and processes depend on the action of light on one or the other of two substances. Light, under certain conditions, blackens certain salts of silver, and hardens certain organic substances, such as gelatine.

By the first action we produce our negatives and print our silver photographs; by the second action we produce printing plates from which we print with ordinary printing ink. The application of this second action is the foundation of the various processes of photo-mechanical printing. All of these depend of course on both actions of light—first, in the production of the negative; second, in the production of the printing plate.

There are four leading lines of photo-mechanical printing methods—photo-engraving, photo-lithography, photo-gelatine, and photogravure. Photo-engraving is understood in this country to mean "cuts to print with type." Photo-lithography is the process by which a stone is prepared for ordinary lithographic printing by photography instead of by hand. In both photo-engraving and photo-lithography the prints must be made in dots or lines, but by an ingenious device the half tone of the photograph is closely imitated. This is effected by breaking up the half tone into a series of very fine dots or lines.

The methods mostly in use by us are those which give a true photographic half tone. These are the photo-gelatine and the photogravure methods. The photo-gelatine process is known under a multitude of names: Albertype, heliotype, artotype, Lichtdruck, Indo-tint, collotype, are some of them, but they all mean the same thing, that is, printing from the surface of a layer of gelatine variously supported, and on which a printing image has been produced by light.

The *modus operandi* of obtaining such an image is, in its broad principles, simple enough. An ounce of gelatine is dissolved in, say, ten ounces of water, at a temperature of 100° Fahr. To this solution is added forty to fifty grains of bichromate of potash and sufficient alcohol to make an easy-flowing liquid. This is flowed over a plate of glass or metal and dried in an oven at a temperature of 120° to 140° Fahr. on a level plate, so that when dry a very thin, even solution of bichromatised gelatine remains on the plate. The gelatine-coated plate is exposed to light under a negative, and now comes in the second action of light. The light passing through the negative hardens the gelatine in the shadows, partly hardens it in the half tones, and produces no effect where it is prevented from penetrating by the opaque parts of the negative.

The gelatine-coated plate, which now has the printing image produced on it, has only to be washed in water to prevent the further action of light when it is ready for the press. It is inked up in the same general method that a lithographic stone is inked. But the sun has been the artist and has drawn the half tone of the photograph as no hand could have done it.

Photo-gelatine printing, to the reader and onlooker, seems to be the simplest thing in the world. On account of the "contrary" character of gelatine, it is in truth the most difficult, as those who have been longest at the work best realise. It will be seen that the reproductions by this process have a character all their own, and for a certain delicacy of result and true photographic effect they are unapproachable.

In the photo-gelatine process it will be seen that a new printing surface or material (gelatine) has been brought into use.

In photogravure, the oldest printing material (copper) and the oldest method of printing is employed, but the action of light takes the place of the engraver's tool. There is not time at my disposal to do more than briefly sketch the processes employed. The result desired to be obtained is an intaglio plate to be engraved by photography and to be used for printing on a copperplate press. In the photo-gelatine process we have described how a plate is coated with a thin, even layer of bichromatised gelatine made sensitive to light. If we prepare this gelatine on a copperplate and after the action of light place the plate with its light-produced image in an etching bath, it is evident that the etching fluid will penetrate the gelatine where the light has not acted, and where, therefore, the gelatine is not hardened. It will penetrate less where the light has hardened the gelatine slightly, and it will not penetrate at all where the gelatine is altogether hardened by light. In this way we have a plate etched more or less deeply according to the gradations of the photograph, and therefore reproducing all the gradations of the photograph. This, very broadly, is the underlying principle of our process of photogravure.

Two essential conditions must be observed, however, in order to make the process practical. In the first place, in using a negative to print on the gelatinised copperplate, it is apparent that the picture would be a negative. Therefore a positive or transparency must be made from the original negative to print on the gelatinised plate, in order that the final picture may be a positive. The other necessity is that there must be a "grain" on the copperplate in order to give it an ink-holding capacity. This is effected by "laying a ground," as in the aquatint method, or by dusting the surface with resin or asphalt which is melted by heat—in both cases, of course, before the application of the gelatinous surface.

The etching fluid does not penetrate these fine points of resin, and the underlying copper is protected and remains in the shape of a number of minute pyramids, which prevent the ink being wiped out. The rest of the process of reproducing photogravure pictures is the ordinary method of copperplate printing, requiring, however, greater skill and care in its execution.

Whilst photo-gelatine printing is marked by the delicacy of its results, the characteristic feature of photogravure is its strength and richness, which may be further heightened in the various steps of the process as well as subsequently by the hand of the graver.

ERNEST EDWARDS.

Foreign Notes and News.

M. A. STREOLITZ gives the following formula for toning platinum paper:—

A.	
Neutral oxalate of potash	2 parts.
Phosphate of potash	1 part.
Water	1 litre.
B.	
Platinum potassium chloride	1 part.
Water	20 parts.

Just before using it, six parts of A are mixed with one part of B, the proofs are washed as usual and then toned. If one wishes to obtain black tints the proofs are placed for from twenty-five to forty minutes in the solution, which should not be shaken, when they will acquire a blue-violet tone which will turn black in the fixing bath. The proofs thus toned keep better than those toned with gold, as they are not affected by sulphuretted hydrogen or other gases. Fixing and washing takes place in the usual manner.

DR. COHN, of Breslau, has succeeded in taking a number of photographs of the eye by means of the magnesium flash light, among others of the eyes of a lady whose pupils had attracted attention by their difference in size. Dr. Cohn concludes that the phenomenon in question is due to softening of the spinal marrow, causing paralysis of the nerve controlling the expansion and contraction of the pupil.

At a recent meeting of the Berlin *Photographischer Verein* Captain Himly (a translation of whose article on *Hydroquinone* was published in a recent number of the JOURNAL) explained and exhibited Stirn's patent chronoscope. This newest form of camera shutter seems, according to his account, likely to be very generally adopted in the near future, especially as it can be employed for ordinary and instantaneous work. For ordinary work the time of exposure, from one to fifty seconds, is regulated automatically by clockwork, which sets the mechanism connected with the shutter in motion at any time desired, by an arrangement familiar to all acquainted with alarm clocks. All counting of seconds or other trouble is thus rendered unnecessary by the chronoscope; and the shaking of the floor, on approaching to put on the cap, which often gives rise to unsatisfactory results, is avoided. Amongst other advantages which were pointed out by those taking part in the discussion must be mentioned the fact, that in cases where long exposures are necessary the camera may be left by itself and some other operation proceeded with.

CAPTAIN HIMLY also read the report of the Testing Committee of Vienna on Lechner's universal hydroquinone developer, from which it appeared that this developer possesses no advantages and contains nothing new.

An article in the *Revue Photographique* discusses the means employed to make hydroquinone solutions "keep." According thereto a mixture of hydroquinone and sulphite is not very permanent. If compounds of soda be employed for developing Eastman's bromide paper, a very disagreeable yellow colouration is produced. The meta-bisulphite of potash is chemically more stable, but difficult to procure. Bisulphite of calcium, however, which is in more general use, and can be procured sufficiently pure and cheap, has been tried as a preserver of hydroquinone with much success. M. de Soehr, who is responsible for the above facts, further states that he added a 20 c.c. of a saturated solution to 180 c.c. of water, and dissolved therein one gramme of hydroquinone. This solution, he declares, proved absolutely permanent. All the ordinary precautions required by hydroquinone must of course be taken when using the above solution, namely, absolute cleanliness and an absence of hypo or iron salts.

Our Editorial Table.

THE CHEMISTRY OF PHOTOGRAPHY.

By PROFESSOR R. MELDOLA, F.R.S. London: Macmillan & Co.

A TREAT of no ordinary nature is in store for the careful reader of this truly excellent volume, which comprises a series of nine lectures, delivered as a special course at the Finsbury Technical College, and

addressed to a mixed audience, composed of chemical students and practical photographers.

Professor Meldola discusses his subject in a manner unlike that of most other writers on photographic chemistry, entering fully and deeply into the principles which underlie photographic action. Each lecture is followed by an appendix indicating experiments to be performed in substantiation of the doctrines enunciated in the text.

In one of his lectures (the sixth) the talented author explains why our modern emulsion processes have such an enormous advantage in the way of rapidity over the old wet plate methods. While the sensitiveness of the emulsion has much to do with it, a certain share is also credited to the developer, which, while it was necessarily acid in the wet process, in which free nitrate of silver was present as a sensitiser, becomes in the gelatine emulsion plate alkaline, and may also be used of greater strength. Some of our older readers may remember that the late Thomas Sutton strongly advocated a bromised wet collodion process, in which all free nitrate of silver was removed by washing, the plate being then exposed for a much briefer period than usual, and developed with an alkaline developer. In giving his reasons why it is safer to employ sodium thiosulphate (hypo) than potassium cyanide as a fixing agent for gelatine plates, the author says that the latter, being always alkaline, has a tendency to soften the film, and, moreover, has a slightly solvent action upon metallic silver, thus tending to reduce the intensity of the image in the medium tones.

The work is one of the "Nature Series;" it contains 370 pages, price 6s.

PRACTICAL AMATEUR PHOTOGRAPHY.

By C. C. VETTER, Leeds.

This is a pamphlet of sixty pages which sells at sixpence. It contains sound information, with formulæ for developing, toning, and the other solutions required in photographic practice. There are also hints on retouching, stripping films, copying, pinhole, orthochromatic and instantaneous photography. It will prove very useful for the beginner.

Fry's Film Slides.

Messrs. SAMUEL FRY & Co., Limited, have brought out a camera slide specially adapted for films, of which each holds two. There is a septum or division which is inserted through an aperture left at one end of the slide, and on each side of this division there is a recess capable of receiving a film and holding it flat. Although the sample sent to us is designated by Messrs. Fry as "only a rough model," and is made of some hard, light-coloured wood, we see no reason why it should not answer as well as mahogany. This one is well designed and well constructed, and from an accompanying price list we notice that it is also cheap.

VOIGTLANDER'S NEW RAPID WIDE-ANGLE EURYSCOPE.

MARION & Co., London, Sole Agents.

Is there any reason why a lens cannot in itself be at once a rapid, a group, and a wide-angle? Most emphatically it cannot—we would have said some time ago, and when optical flint and crown glass formed the materials of which our lenses were constructed. But *tempora mutantur*. We well recollect a conversation with Herr Voigtlander at the Crystal Palace Photographic Exhibition in the early spring of 1888, in course of which he told us of certain valuable, although at that time scarcely recognised, properties inherent in some of the stable samples of Jena glass, and which he had taken advantage of in the construction of certain lenses then being exhibited for the first time, and to which reference has been subsequently made in these pages.

This able optician has now made another departure from the beaten track in optical construction, and one which must prove of exceptional value, more especially to photographers whose studios are short, or those who desire to take a group without possessing the facilities for getting their cameras removed to such a desirable distance, as with an ordinary lens, will insure all the figures being introduced. The definition is unexceptionable. The new lens is one which possesses the property of working with an aperture slightly larger than the general run of the rapid doublet series, it being $f.7.5$; it is, therefore, well suited for portraits. But on slightly moving a lever, which projects through a slot in the side of the tube, an iris diaphragm comes into action, and the aperture may be diminished to a minimum whenever desired. Its large aperture and short focus render possible the including of an angle unusually large ($\approx 90^\circ$), and this with a very brief exposure, hence its utility for groups in studios of limited exten-

sion. Comparing one lens with another, this new rapid wide-angle euryscope includes 10° more of angle than the usual rapid euryscope of the same maker.

This new addition to the optical resources of the photographer will not fail to secure a warm place in the affections of the brotherhood. Messrs. Marion & Co., Soho-square, W., are the agents for this and the other productions of Herr Voigtlander.

PATENTS COMPLETED.

IMPROVEMENTS IN AND CONNECTED WITH PHOTOGRAPHIC CAMERAS.

No. 10,823. WALTER O'REILLY, Edgware-road, Middlesex.—*July 26, 1888.*

This invention has for its objects to provide a cheap, diminutive, simple, and easy means of producing instantaneous photographs (to be taken in the open when necessary) and to dispense with a dark room or changing box.

Also a novel and simple instantaneous shutter.

In carrying out my invention I use for the ordinary dark back a metal receptacle of a suitable size and shape to receive the sensitive plate, and I attach thereto a tube or hollow projection made of some suitable material, in which, in a proper position, I place a simple or compound lens of glass or other transparent material so as to form a sharp image of the object to be photographed on the sensitive film.

I use for my combined cap and exposing shutter a disc closely fitting on to the end of the tube containing the lens.

This has a motion of opening and shutting imparted to it by the combination of two springs and a catch, i.e., the hinge of said shutter I preferably make of indiarubber strip, so that the tendency is to keep the disc shut.

The disc has attached to its edge near to the hinge a pin or projection on to which is engaged another spring, which may be spiral, loop, or other form, which tends to open the shutter, and it is stronger in its pull than the spring which keeps the shutter closed.

There is a catch placed in a suitable position, which prevents the stronger spring from opening the shutter, but which may be released by any of the well-known methods.

The result is that on releasing the retaining catch the shutter is pulled open by the stronger spring, but in this act the stronger spring disengages itself from the pin and the weaker spring pulls the shutter back again.

Another feature in my invention is the mode of introducing and abstracting the sensitive films, and consists in slipping a small light-proof bag containing the film on to the mouth of the dark slide, exposing it, and re-slipping the film bag into the bag, there being thus no chance of spoiling the said film by undue exposure.

While the picture is being taken the bag is held in position by two side springs or other contrivance.

I provide for showing which is the sensitive side of the film or plate by a mark or projection or indent on one side of the bag.

AN IMPROVED COMBINATION RECEIVING, DELIVERING, AND DISTRIBUTING APPARATUS FOR PHOTOGRAPHIC COATING MACHINES.

No. 5650. JAMES WILLIAM THOMAS CADRETT, Greville Works, Ashstead, Surrey.—*April 2, 1889.*

This invention has for its object to facilitate and insure the even and regular delivery and distribution of photographic emulsion on to and over glass or other surfaces to be coated therewith, thus obtaining thereon a film of uniform consistency.

To effect this I fit a coating machine with a combination receiving, delivering, and distributing apparatus, consisting of a combined trough and roller. The roller is formed on or fixed to the front of the trough, so as to form a cylindrical or curved lip thereto. Such cylindrical or curved lip may be either tubular or solid, while the line of its upper surface is preferably at a somewhat lower level than the line of the back of the trough. Suitable grooves or guides are formed or fixed on the inside of the trough at each end. Into these grooves or guides a division plate is fitted, thus dividing the trough into two longitudinal compartments. This division plate has suitable apertures formed therein, so that when the emulsion is fed into the trough it first enters the back compartment and then flows through such apertures into the front compartment, and gradually rises therein until it wells over the cylindrical or curved lip on to the glass or other surface to be coated with the emulsion. Or such lip may be fitted with a plate or other suitable equivalent, which is so placed as to form an inclined plane on to which the emulsion may flow, and thus be delivered in a sheet on to the surface or surfaces to be coated therewith.

Or the division plate may, if preferred, be made solid, and so fitted that a narrow opening is left between its lower edge and the bottom of the trough to allow the emulsion to flow under and into the front compartment, and gradually rise therein until it overflows the cylindrical or curved lip of the trough in the manner already described. I would here observe that I take care so to arrange the opening or openings in or under the division plate, that the emulsion shall

pass through or under such division plate at a level below the level of the emulsion in the back compartment, so as to avoid the generation of air-bells or bubbles.

In order to confine the overflow within proper limits, I paint the exterior surface of the cylindrical or curved lip either wholly or partially with emulsion, the portion so painted corresponding in width with that of the plate or other surface to be coated. By this means I cause the emulsion to rise and flow over the cylindrical or curved lip on to the surface to be coated therewith, at the same time that such overflow is limited in extent to the width of such painted surface.

When the division plate is perforated, I prefer to cover the same with a strainer of muslin, gauze, or other like fabric, through which the emulsion percolates as it passes into the front compartment of the trough, thus regulating its flow.

Either the division plate or strainer or both may be dispensed with and only the trough with a cylindrical or curved lip employed, but it will be found in practice that more accurate results are obtained by employing the apparatus complete.

The apparatus is mounted in suitable bearings, and is so arranged and fitted that its relative position to the surface or surfaces to be coated can be regulated and adjusted as desired. If desired, the cylindrical or curved lip may be covered with muslin or gauze or other like fabric.

My improved apparatus may be fitted to any photographic coating machine, provided that it be placed transversely to the plane of travel of the plates.

The claims are:—1. The combination receiving, delivering, and distributing apparatus, for coating glass and other surfaces with photographic emulsion, consisting of a trough provided with a cylindrical or curved lip, and fitted with a division plate and strainer, all substantially as hereinbefore described and shown. 2. As a secondary form of such combination receiving, delivering, and distributing apparatus, a trough furnished with a cylindrical or curved lip, and fitted either with a division plate or a strainer, substantially as hereinbefore described and shown. 3. As a primary form of such combination receiving, delivering, and distributing apparatus, a trough furnished with a cylindrical or curved lip, substantially as hereinbefore described and shown. 4. Fitting such combination receiving, delivering, and distributing apparatus, with a plate or other equivalent device, so as to form an inclined plane for the delivery of the photographic emulsion on to the surface or surfaces to be coated therewith, substantially as hereinbefore described and shown.

AN IMPROVEMENT IN REVOLVING PHOTOGRAPHIC CAMERAS.

No. 6886. CARL PAUL STIRN, 20 Park-place, New York, United States of America.—April 25, 1889.

My invention relates to that class of photographic instruments in which the camera is made to revolve during exposure, so as to obtain a panoramic view of the entire scene encircling the camera or of any desired portion thereof.

It consists in improved devices for moving the camera, and in a novel construction and arrangement of its parts, as hereinafter described and claimed, and has for its object to simplify the apparatus and render it more compact and efficient.

[Probably the precise nature of this revolving camera will be ascertained with sufficient fulness from the claims, which are as follows:—1. The combination with a photographic camera revolving upon a pivotal axis of a motor mounted upon the instrument to produce its revolution, substantially in the manner and for the purpose herein set forth. 2. The combination with a photographic camera, revolving upon a pivotal axis and motive mechanism actuating the same to produce its revolution, of an automatic stop to arrest its movement at each complete revolution thereof, substantially in the manner and for the purpose herein set forth. 3. The combination with a photographic camera, revolving upon a pivotal axis and motive mechanism actuating the same to produce its revolution, of an auxiliary adjustable stop to arrest it when it has made a partial revolution after being released from the first stop, substantially in the manner and for the purpose herein set forth. 4. The combination with a photographic camera, revolving upon a pivotal axis and motive mechanism actuating the same to produce its revolution, of the film-supply spool and the film-winding reel mounted within said camera, an intermediate guide roller geared to revolve in unison with the instrument, and over which the film is carried in passing from the spool to the reel for exposure, and pins on said roller made to engage the film to prevent its independent movement over the same, whereby the film is moved in synchronism with the movement of the camera, substantially in the manner and for the purpose herein set forth. 5. The combination with a photographic camera, revolving upon a pivotal axis, and with a film-supply spool and a film-winding reel mounted therein, an intermediate guide roller over which the film is carried and by which it is engaged, and a wheel fixed upon the pivotal axis of the camera and geared to said guide roller, of a motor geared to the film-winding reel to turn it, whereby the movement of the film, automatically produced by the motor, will cause a simultaneous revolution of the camera, substantially in the manner and for the purpose herein set forth. 6. The combination of the winding spindle, the coiled spring attached thereto at one end and to a fixed support at the other, a ratchet fixed upon said spindle, a toothed wheel revolving loosely thereon, a pawl carried by said wheel and engaging said ratchet, a stop to lock the wheel, the reel spindle mounted parallel with the winding spindle, the pinion upon said reel spindle gearing with the toothed wheel on the winding spindle, the head carried by said reel spindle, the detachable film-winding reel adapted at one end to be coupled to said head in alignment with the spindle, and the longitudinally adjustable pivot pin engaging the opposite end of the reel to serve as a prolongation of its axis, all substantially in the manner and for the purpose herein set forth. 7. The combination with the head of a camera stand or tripod, and with a toothed wheel fixed thereon, of a plate mounted to revolve upon the axis of said fixed wheel, a camera mounted upon said plate with the optical centre or transverse axis of the lens directly in line with the pivotal axis of the plate, a film-carrying roller mounted in the camera having devices for engaging the film led over it, a pinion fixed to the shaft of said

roller to gear with the fixed wheel on the stand, a film-supply spool on one side of said roller, and a film-winding reel on the other side thereof, whereby, as the film is moved by the action of the winding reel, the camera will be simultaneously revolved upon its axis, substantially in the manner and for the purpose herein set forth. 8. The combination with the head of a camera stand or tripod, the toothed wheel fixed thereon, the revolving plate pivoted to turn upon the axis of said wheel in proximity thereto, the camera secured upon said plate, a pinion mounted upon the camera and meshing with said toothed wheel, and a motor carried by said camera and geared medially to said pinion, of the elastic radial arms pivoted to turn independently upon the axis of the toothed wheel beneath the same, and the pins projecting from said arms to pass severally through either of a series of holes in the rim of said toothed wheel and into engagement with a single hole in the face of the overlying revolving plate, substantially in the manner and for the purpose herein set forth. 9. The combination in a photographic camera, with the exposing slit and the film-guiding rollers by which a sensitised film is held taut over said slit, of a perforating bar mounted to reciprocate transversely to and from the line of movement of the film and having perforating points projecting therefrom to penetrate the film when the bar is pressed towards it, substantially in the manner and for the purpose herein set forth.]

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

A MONTHLY technical meeting was held in the small room attached to the Gallery, 5A, Pall Mall East, on Tuesday last, the 25th instant,—Mr. John Spiller, F.C.S., in the chair.

The CHAIRMAN, in making reference to the paper recently shown by Mr. Warnerke, and which only requires treatment with water after exposure in the printing frame, pointed out that iron was present, and a salt of this metal is apparently the sensitive material. The paper does not contain uranium, mercury, platinum, gold, or silver. All his efforts to tone the reddish image and to thereby obtain anything more agreeable than the rust-coloured image had been fruitless. The unexposed paper is instantly blackened all over by treatment with sulphide of ammonium. Mr. Spiller said his experiments had been far less complete than might have been desired, but he only had a piece of the paper about two inches square.

There was a good deal of conversational discussion as to the prints obtained by iron methods by Robert Hunt in the early days of photography.

Mr. FRIESE GREENE said that a simple solution of hydroquinone will serve well to clear yellow gelatino-bromide negatives or prints on gelatino-bromide paper. After fixing and washing, an immersion for a few seconds in a solution of hydroquinone—one part of a ten per cent. solution in sixteen parts of water—will clear away all yellowness. A moderate washing serves to remove the hydroquinone.

The next meeting will be the monthly technical meeting of July 23, an interval of four weeks.

After the formal meeting had terminated the desirability of organizing an outdoor meeting on the afternoon of the second Tuesday in July was discussed and generally approved of.

NORTH LONDON PHOTOGRAPHIC SOCIETY.

JUNE 18.—Mr. A. Mackie (Vice-President) in the chair.

Messrs. G. A. Powell, M. P. Powell, and F. W. Teversham were elected members of the Society.

Mr. B. B. FULLER showed some negatives taken at the excursion to Waltham Cross which were stained a uniform yellow-brown colour, which he wished to know the cause of. They had been put into an alum and acid bath without being washed after taking them from the hypo fixing bath.

The CHAIRMAN replied that this would probably be the cause of the stain, sulphur being deposited in the film.

Mr. G. J. Clarke showed an enlargement on the Ilford slow bromide paper, and also some very fine lantern slides from prints in an old book.

The CHAIRMAN stated that he had made some lantern slides from 10×8 prints, the method he adopted being to wet the prints and squeegee them on to glass; they were then copied through the glass and, being reduced to lantern size, were very sharp.

In answer to a question about lenses for copying, the CHAIRMAN said that he used a portrait lens, the focussing being much more easily effected with the full aperture of such a lens than with a slow one.

Mr. W. BISHOP showed a dropping bottle from Maw, the chemist, which he found very useful, the bottle being held upside down in the hand, the heat of which caused the air inside the bottle to expand and drive the solution out drop by drop.

Mr. W. Few showed a Thornton-Pickard instantaneous and time shutter which worked with a flexible blind.

Mr. W. Bishop showed a print by Mr. V. Blanchard's platinum toning process, and also some prints on albumenised paper toned by the same means.

Mr. CLARK having referred to the uranium plates, the CHAIRMAN stated that he had used them some years back and found them give very fine negatives, the colour of the image quite distinguishing them from ordinary plates.

During a short discussion on halation, the CHAIRMAN said that, in his opinion, the extent to which this was present in plates depended in a great measure on the development, it being possible to get any amount of halation from some subjects if the development were not suitable. For special subjects he recommended backing plates with burnt sienna ground in water, procurable at any oil shop, and mixed with gum-water to prevent its powdering off; a little methylated spirit added would make it dry quicker. This could be applied with a brush, or an indiarubber roller could be used.

Mr. J. Groundwater showed a Voigtlander's orthographic lens, the small back lens used lengthening the marginal rays, thus making the field very flat. The diaphragm in this case was behind the lens.

The CHAIRMAN remarked that this was a very good form of lens, and was much used formerly, when rectilinear lenses were very expensive.

On Saturday, June 29, there will be an excursion to Enfield, meeting at the Great Northern Railway Station. Train, first arriving after three p.m.

The next meeting will be on July 2, when there will be a discussion on *Defects in Plates*.

NORTH SURREY PHOTOGRAPHIC SOCIETY.

JUNE 18.—Mr. VALENTINE BLANCHARD gave a demonstration of his new platinum process, which was greatly admired by the members present; questions were freely asked and some discussion entered into.

The HON. SECRETARY announced the subjects of five prizes for competition during the next session, beginning October 8, to which date the Society adjourns its formal meetings; informal conversational meetings will be, however, held fortnightly during this recess.

The meeting then joined heartily in wishing one of its members, Mr. Bell-Smith, a pleasant journey home to America, where he is returning after a nine months' sojourn in this country.

Mr. BELL-SMITH replied as follows:—As this is the last opportunity I shall have of attending a meeting of any photographic society in England before my departure for America, I cannot let it pass without giving expression to the appreciation which I feel for the many courtesies which I have received at the hands of the various photographic organizations which it has been my good fortune to visit. When I came to England, nine months ago, and began my series of public demonstrations it was not without some feeling of trepidation. I had heard, and have since had ample chance to verify, that the English amateur photographer was an extremely intelligent and well-informed man, and well posted in the art of picture making, and, therefore, if any one had anything to show them it must be genuine and of first-class merit in order to command their consideration. I had not long to wait to find that the subject of my demonstrations was one in which a great deal of interest was taken, and it has been a source of great pleasure to me to find that my efforts have been appreciated. Everywhere I have visited I have been treated with the utmost kindness and attention, in many cases I have been entertained in a manner that was exceedingly flattering; and I assure you that in returning home to America I carry with me recollections of a very pleasant and agreeable character that will not soon be forgotten.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

JUNE 20.—Mr. B. Karleese (Vice-President) in the chair. There was a large attendance.

The HON. SECRETARY announced that excursions would be taken on July 13 (half day), to Tamworth; July 22 (whole day), to Shrewsbury; July 27 (half day), to Worcester; and that pictures for the Whit-Monday competition must be sent in to the Hon. Secretary (Mr. J. H. Pickard) not later than July 4, for transmission to the special Judges selected by the Council.

Dr. J. C. HUXLEY then gave his paper on *Platinotype*. He commenced with a short description of the chemistry of the process and a recapitulation of the various failures which might beset the tyro at starting, explaining the reason why, and how they may be avoided, &c.; then proceeded with a practical demonstration of the hot process, giving minute details and producing very fine pictures. The cold process was then gone into; and, lastly, the Pizzighelli paper. On comparing the results, the hot process received the most favour. In conclusion, he offered help to any member wanting further information in the manipulation of these processes.

In the discussion which followed, Mr. A. W. Wills, J.P., asked what sort of negatives were required for this platinotype process. He had tried it, and, to his idea, had failed with it. He considered his attempts produced flat, stale, and unprofitable pictures. He had been informed that his negatives wanted more "pluck," and had a want of contrasts of light and shade. Now he always endeavoured to obtain delicate negatives (without violent contrasts), and these gave him excellent silver prints.

Dr. HUXLEY, in reply, said Mr. Wills's negatives would give good platinotypes; in fact, a negative from which it was difficult to obtain a silver print would yield, by proper treatment, a good platinotype. He always sensitised his own paper (hot process), and when using a thin negative or one void of great contrast of light and shade he sensitised with a weak solution, and for a negative with great contrast a strong sensitising solution. (He here demonstrated the sensitising of the paper.) The full instruction, with paper and solutions, can be obtained from the Platinotype Company.

The fine results of these beautiful processes and the practical instruction given by Dr. Huxley was much commented upon by those present.

After the discussion, Mr. W. J. HARRISON, F.G.S., moved, as a recommendation to the Council, "That this Society endeavour to organize a photo-

graphic survey of the county or parts of the county of Warwickshire." Mr. GEORGE A. THOMASON seconded, and it was carried *nem. con.*

Portrait Painting as applied to Photography is the subject of Mr. G. J. Serchall's paper on July 18.

LEICESTER AND LEICESTERSHIRE PHOTOGRAPHIC SOCIETY.

JUNE 20.—Several members and friends, to the number of thirty, having chartered a saloon carriage on the Midland Railway, journeyed to Rowsley and from thence by carriage to Haddon Hall, being joined at Loughborough by a few members and friends connected with that Society. The weather was fine, and the party soon commenced work. Several good negatives were secured, and the return to Rowsley was commenced, where the party had tea. On the return journey they were met at Derby by several members of the Derby Photographic Society, inviting their attendance to an art exhibition in connexion with their Society. Time, however, not permitting, it was, with many regrets, resolved to postpone the pleasure, and to appoint a special evening for a visit to our Derby friends. One hundred and ten plates were exposed by the members, ranging from 10×8 to half-plate, with, as far as has been ascertained, excellent results.

Correspondence.

Our Correspondents should never write on both sides of the paper.

DAMAGED IN POST.

To the EDITOR.

SIR,—I sent some photographs through the post the other day and they are returned to me damaged. Will you, please, tell me who will have to pay?—I am, yours, &c.,
W. C.

[See leading article in present issue.—Ed.]

RENDERING GELATINE SURFACES ELECTRICALLY CONDUCTIVE.

To the EDITOR.

SIR,—The letter of Mr. Henry E. Davis, in last number, prompts me to say that it would be very desirable if some one would give us a practical disquisition on the best means of giving gelatine reliefs a conducting surface.

I used, several years ago, to have a fondness for making engraved copper plates from raised (or sunk) gelatine *clichés*, and for some time I was a good deal troubled in imparting to the gelatine a surface which should prove a conductor so good as to insure an almost instantaneous primary deposit of copper before the solution in the depositing cell should exercise any action upon the delicate image on the gelatine. Among the methods tried, some of them with entire success, was brushing over the surface with a mixed aqueous and alcoholic solution of nitrate of silver, and immediately reducing this to the metallic form by sulphuretted hydrogen. Phosphoric fumes were also utilised for this purpose.

Some of the bronze powders made by Bessemer also form good conductors, any or all of them being superior, in my estimation, to plumbago.

I once prepared, from pen-and-ink drawings, the whole of the cuts by which one of our medical works is illustrated, but in this case I took plaster casts from the raised gelatine (which was spread upon glass plates to receive the exposure), and prepared the printing surface alone by electrolysis. Paul Pretsch or Duncan C. Dallas, I am uncertain which, prepared gutta-percha with pitch in such a manner as to be useful for taking clean, sharp impressions from moist gelatine. Does any one know this method now?—I am, yours &c.,
ST. OLA.

Exchange Column.

* * No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Wanted, light portable whole-plate camera and lens in exchange for tricycle.—Address, E. F. USKESWOOD, Dorking.

Wanted, whole-plate camera with dark slide in exchange for a large camera in good condition, size 14×14, brass bound, leather bellows.—Address, A. SMITH, 233, Usbridge-road, Shepherd's Bush.

Tourist camera, 7½×4½, with leather bellows, all movements, and extending front, also Dallmeijer's rapid rectilinear lens with diaphragms; will exchange for a good quarter-plate set and difference adjusted.—Address, C. HARRISON, 13, Neal-street, Bradford.

- Half-plate camera (Menger's), three double backs, whole-plate lens, stand, &c.; exchange, tricycle.—Address, C. GIMMONS, 2, Avenell-road, Highbury, N.
- Wanted to exchange, a Lancaster's quarter-plate 1889 Instantograph, with two extra slides and Lancaster's Universal stand, for half-plate camera as above (must be 1889); will give a little cash.—Address, GEORGE J. WOODWARD, 17, Palmerston-street, Moss Side, Manchester.
- Will exchange rolling platform, six feet by three feet, for half-plate wide-angle lens; also Voigtlander's ten and a half inch focus orthoscopic lens and quarter-plate portrait lens for half-plate rapid rectilinear lens.—Address, R. S. JOHNSON, Photographer, Saxon-street, Dover.
- Will exchange a six-inch compound condenser in brass cell (new), two backgrounds (one interior and one exterior), also tree eight feet high, for a dissolving view apparatus or whole or half-plate landscape camera.—Address, COOPER & Co., Market-entry, Church-street, Inverness.

Answers to Correspondents.

* Communications relating to Advertisements and general business affairs must be addressed to "H. GREENWOOD & Co.," 2, York-street, Covent Garden, London, W.C.

All matters for the text portion of this JOURNAL, including queries for "Answers" and "Exchanges," must be addressed to "THE EDITOR," 2, York-street, Covent Garden, London, W.C. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.

PHOTOGRAPHS REGISTERED:—

P. Godfray, Jersey.—Two photographs of the Harbour and one photograph of the Esplanade, Jersey.

E. Brightman, Bristol.—Photograph of a sailor, entitled "An Old Salt."

J. H. LONDON.—So far as we are aware, dry plates specially adapted for positive pictures are not at the present time made commercially.

POET.—A series of articles on retouching, from the pen of Mr. Redmond Barrett, appeared in our volume for 1887; you cannot do better than study them.

A. W. A.—the crystals of hyposulphite of soda are discoloured, wet, and have an unpleasant smell, you may be sure that the salt is quite unfit for photographic purposes.

STILL.—It is quite correct that a licence is required even to distil water. The licence to use a still is ten shillings a year, but it must not be used for distilling or rectifying spirit.

W. B. S.—From an announcement in "Our Editorial Table" last week you will perceive that yellow-tinted screens for use with orthochromatic plates can be obtained from Mr. J. R. Gotz.

OPERATOR asks if the "dusting-on" process is a really good process for making reversed negatives, and, if so, where working details are published. The process is well suited to the work, and full working details will be found on page 466 of our volume for 1885.

R. R. R.—So far as we are aware, the Stannotype patent is still in existence. If this be the case, of course the process cannot be worked except by a licence from the holder of the patent. The Woodburytype patent has expired, and that process is open to all.

A. R. W. inquires which is the best for rendering paper prints transparent for colouring from the back, ordinary paraffin wax or bleached beeswax (virgin wax).—Of the two the paraffin is preferable, inasmuch as it is not so prone to turn yellow with age. The method of application is the same in each case.

ROSE.—As a rule, better photographs of flowers can be obtained with orthochromatised plates and a tinted glass screen, as you suggest, than on ordinary plates. The major portion of Mr. Henry Stevens's pictures were on ordinary plates, and the greater number of Mr. and Mrs. Payne's works were by the wet collodion process.

D. MILLER (Chicago).—Several articles have from time to time appeared on the subject, but they have been more or less suggestive. The most successful "workers in the production of typographic blocks in half-tone" keep the details of their processes as strict trade secrets. Possibly some of them might give you instruction for a suitable consideration.

AN AMATEUR OF TWO YEARS' EXPERIENCE.—The pictures are all very good as photographs, but, in many instances, they are defective as pictures owing to the composition. The chief fault in all is the foregrounds, which are blank and barren. If in the majority of the examples sent, an inch or an inch and a half of the foreground were trimmed off, the pictures would be much improved.

A. N. Z. says that he recently tried the back of a portrait lens for views in the same manner as he has been using the back lens of a "rapid symmetrical," but he could not get a sharp image.—This is not surprising. It is the front lens of a portrait combination that must be employed as a view lens, and with the convex side next the ground glass. Thus arranged it forms a good landscape lens.

CAUSTIC.—No definite proportion has been determined in which to add carbonate of ammonia to the hypo fixing bath. Very little suffices to remove the organic silver compound from the albumenised paper. In your case too much was probably added.

RUSTY.—So far as we can judge from the appearance of the prints, they should tone to a good colour. We strongly suspect you are over-toning for this sample of paper. From your description, we should surmise the sensitising bath is more acid than is desirable. Why not try another brand of paper, if you cannot get the tones you desire with this? We do not understand your meaning—"a trace of hypo in bath."

A. C. SINCLAIR inquires what is the heliotype process which was worked extensively some years ago, but has now, apparently, fallen into oblivion. He adds that "some of the very best photo-mechanical pictures I have ever seen were by this process."—The heliotype process is simply another name for collotype. As it was practised under this name many years ago, it differed somewhat in detail from the usual method of working, inasmuch as the printing film was stripped from the glass plate on which it was prepared and mounted on to one of metal. Now the prints are, as a rule, taken from the gelatine film when it is on the glass.

F. E. inquires: "1. Does the method of dividing the equivalent focus of lens by the diameter of stop give the ratio of speed of stop near enough for practical purposes with a rapid doublet lens of short focus (about four-inch)? I have a lens sent me in which the diameters of stops are smaller than they should be (according to the above rule), as marked by the makers; for instance, the lens is four and one-eighth inches equivalent focus, the stop marked $f/8$ measures only five-twelfths of an inch in diameter, which, according to rule, is about $f/10$; the other stops are in the same proportion. —2. Are they wrongly marked?"—1. Yes.—2. Wrongly marked.

A YORKSHIRE PHOTOGRAPHER writes as follows: "Some two years ago a clergyman in this neighbourhood sat to me for his portrait in his robes, the first and only time he had ever had his portrait taken. You were kind enough to make it copyright for me and I have sold a good number. Recently he has sat to a London firm, also in his gown, and a stationer here is selling copies. Can I not prevent him, as the portraits are in nearly the same position as mine and in the same costume?"—Certainly not. The gentleman can give sittings to as many photographers as he likes, and they can all make their work copyright if they choose. You cannot have a copyright in a man's face, though you may have in your photograph of it. If this be pirated the law will give you protection.

HACKNEY AMATEUR.—Yes, we did receive the lines written by Mr. Hubert. If or when the poetical gift is farther developed, and our friend becomes a Tennyson or a Longfellow, we imagine that he, looking back upon earlier efforts, will thank us for not crediting him with fourteen verses of which the following are average specimens:—

Printing takes only one-third the time	Results so fine which will last
Than the process of albumen fame;	In their kind quite unsurpassed
The advantage above all,	The Hackney Photo Club can't miss
Ease in working I should call.	In all its stages to discuss.

With a little more of the divine afflatus, and, possibly, the aid of a little calligraphic retouching, the author of the above will yet equal that of some high-toned verses which in bygone times used to adorn one of the American Western photographic journals.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Report received too late for insertion in this number.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting of this Club, July 3, 1889, will be on *Copying*. Saturday outing at Hanwell.

MR. W. F. STANLEY has shown us an enlarging lantern he is manufacturing, or, to be more strict, that portion which serves to hold and illuminate the negative which is to be either enlarged or reduced. The body consists of a pyramid of a somewhat obtuse form standing on one of its sides, the inside of which is painted white. At the apex of the cone a magnesium ribbon is introduced, and this, when ignited, illuminates the sides of the cone, which forms thus a luminous white background for any negative placed in a suitable holder at its base. A metal shield interposed in front of the flame prevents any of the direct light from falling upon the negative. Any suitable camera may be employed in the enlarging or reducing of the image. The impression conveyed by the examination was favourable as to its serving the purpose intended in an efficient manner.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1522. VOL. XXXVI.—JULY 5, 1889.

PHOTOGRAPHIC LENSES AS TELESCOPE OBJECTIVES.

SPECIAL attention was directed by Mr. A. Mackie at the meeting of the North London Photographic Society on Tuesday last to an article of a somewhat extraordinary nature which appeared among the general contributions to one of the American photographic annuals for 1889, and in which the writer gravely recommends the utilisation of the back lens of a portrait objective as an object glass for a telescope, and an astronomical one at that. Well might Mr. Mackie have designated the suggestion as absurd, and well might the President have said that it was impossible the writer could have known anything about telescope object glasses, or even of the properties of the very lens he was recommending, else would he have foregone the pleasure of seeing himself in print in connexion with such a recommendation.

To imagine that the back combination of a portrait objective will serve as an object glass for a telescope is simply nonsense. Such a lens is an uncemented compound with a considerable air space between its component parts, and must of necessity have a large excess of negative spherical aberration to compensate the opposite kind of aberration of the front lens and flatten the field. It is, in fact, a correcting lens, and as to making the object glass of a telescope of it, much better to have borrowed the glass of a cast-off pair of his grandmother's spectacles, which would much better answer the desired purpose.

On referring to the article in question, we find that the author (whose name we suppress out of kindness) starts by saying that "Most photographers do not know that an excellent telescope can be constructed out of the lenses in common use in their galleries, but such is the case. The back lens of an ordinary portrait combination makes a very good objective, while a useful eyepiece can be made of an ordinary short-focussed plano-convex lens, costing but a few cents." He proceeds—"A well-finished objective, three inches in diameter, is worth at least fifty dollars;" and then goes on to say that the simplest way to construct a telescope is to unscrew the back lens of any good portrait combination and mount it in a tin tube blackened inside to prevent reflection. A diaphragm one inch in diameter is placed eight inches behind the lens, of which no diameter or focus is mentioned. An eyepiece is then placed at the further end of the tube and the telescope is complete.

This is just about as loose a way by which to construct a telescope out of a photographic lens as any of which we have ever been made aware, and it is one which will yield the worst results that one could well desire. With a whole-plate Darlot

back lens (about three and a quarter inches diameter) the writer says he has distinctly seen the four moons of Jupiter. Will it surprise him to be informed that the same phenomenon can be observed by one of the cheap opera glasses, and in a clear night by a sharp-sighted observer without any extraneous optical aid at all? Certainly there is no stereoscopic lens employed at the present day which will not with a suitable eyepiece show the Jovian satellites.

But the writer in question has just missed making a species of discovery. He employs the *back* lens of a French portrait combination. Let him remove the back lens altogether, and use the front lens convex side out, or next to the stars, and let him then employ a stop or diaphragm placed moderately near to the lens, so as to cut off some of the positive spherical aberration, and he will thus have a decent makeshift for an astronomical object glass. The *front* lens of a portrait combination, which is approximately of a plano-convex form, may be employed most usefully in other directions than that primarily intended; but the *back* lens when used alone in its combined form is, as our American friends tersely abbreviate it, "*n. g.*" What we have here said applies only to the portrait lens.

NEGLECTED PROCESSES—STANNOTYPE.

It is not a little surprising that the above process has, up to the present time, received so little attention on the part of photographers, seeing the excellent results it is capable of yielding. However this is not the only process, as most of our older readers are aware, from which great things were expected at the time of its introduction that has shared a similar fate. Other processes capable of producing, by mechanical and other means, prints which are equally as good as those in silver, have, like the stannotype, passed practically into oblivion. But for the necessity of the powerful and costly hydraulic press, and that the process was hampered by a patent, it used to be said that the Woodburytype would be largely worked by the profession generally. However, the patent has long since expired, and this beautiful process is now only worked by a few large firms.

When the stannotype—which is analogous in principle to the Woodbury process and capable of giving as good results, and which dispenses with the expensive hydraulic press—was first introduced, many were sanguine enough to predict that it would be extensively adopted by professional photographers, especially by those who required large numbers of prints for publication. As a matter of fact however, notwithstanding all that was predicted for it, and the excellence of the results

obtainable by it, we venture to say that at the present time the process is not being worked commercially by half a dozen people throughout the kingdom.

For the benefit of our younger readers who are not familiar with the two processes, it may be as well to explain wherein they differ, particularly as we have had several inquiries about the stannotype process of late. In the Woodburytype process a gelatine relief—essentially a carbon print in high relief—is made from a negative, and from this an impression is taken, in lead, in a powerful hydraulic press, a pressure of several tons per square inch being necessary. This lead impression, or mould, forms the printing plate. The printing process is this: The leaden mould is fixed in a press made for the purpose, a little ink composed of a warm solution of gelatine and pigment is poured on the mould, a piece of paper is laid on, and the lid of the press closed. This forces away all the ink, except that in the intaglio portions, so that when the ink has gelatinised, a perfect cast in the pigmented gelatine is obtained.

The printing in the stannotype process is conducted in precisely the same manner as in the Woodburytype, but the mould is different. Instead of a metal mould being made from the gelatine relief, the latter itself is employed as the printing mould after it has been protected by tinfoil. For durability the tinfoil is previously faced with nickel, steel, or other hard metal. Of course, as the gelatine relief itself forms the printing matrix, it must be made from a transparency instead of a negative, as in the Woodbury process.

Theoretically this method of procedure possesses some advantages over the Woodburytype, inasmuch as one is more independent of the character of the negative. In the latter process a vigorous negative is essential to the obtaining of sufficient relief in the gelatine. Hence a feeble negative may often have to be reproduced before it can be employed successfully. But when the gelatine relief is made from a transparency, the latter can, in its production, be made to any required density. From the above brief outline of the two processes it will be seen that in the stannotype the only things necessary for its working, which are not possessed by every photographer, are the printing presses, and these are by no means expensive, half a dozen or so being obtainable for a few pounds.

Some of the finest lantern slides produced are those by the Woodburytype, and, of course, equally as good ones may be made by the stannotype process. The great beauty of Woodbury slides is the extreme transparency of the shadows. Added to this the colour may be modified at will by the use of different pigments, and the density can be varied to any extent, according to the amount of colouring matter added to the ink. In making lantern slides no press is required in the printing. It suffices to simply press the piece of glass on to the inked mould for a few seconds, and then allow it to remain *in situ* until the ink has set. The same method of printing is pursued in making lantern slides by the stannotype process.

It will now be seen that in working the stannotype process for making lantern slides no other appliances are necessary beyond what are already in the possession of every photographer, be he amateur or professional. It goes without saying, if only one or two lantern slides were required from a negative, that either the Woodburytype or the stannotype would be a troublesome method of making them. But when a number are required the case is different; for when once the printing mould is obtained any number of slides can be quickly produced, with the certainty of their being all exactly alike. Furthermore, with

the same mould any variety may be obtained at will, simply by changing the pigment or varying its proportion.

Full working details of the stannotype process will be found in a series of practical articles in our volume for 1884, to which those interested in the subject are referred.

IN *Nature* last week is to be found an excellent engraving from a photograph of Professor Mendeleef, the eminent savant who recently paid a visit to this country. But the picture possesses some remarkable and objectionable points that may here be referred to, namely, in the manner in which the texture of hair is rendered. Almost the whole of the hair on the upper portion of the head is engraved so as to represent nothing so much as thin macaroni. The beard and moustache are excellent representations of the effect produced in a photograph when a sitter has moved his lips during the exposure, and so interfered with definition. Very likely the learned Professor moved while being taken, and so presented a problem to the engraver, the solution of which offers still another proof, if such were wanted, of the validity of our objections to the use of engravings from photographs, instead of mechanical photo-prints from the negatives themselves, for illustrating scientific phenomena. If it were possible to go so far from veracious representation of a familiar object, as happens in this portrait, to what extent are the pretty engravings trustworthy in regard to unfamiliar sights and material evidences?

THE material composing the sizing used for the papers employed in photography—silver printing especially—has always been understood to exercise an important influence on the character of the print and the mode in which the paper can be worked. Thus, a portion of the reputation enjoyed by Rives paper has been put down to the use of "resin size." It is clear then that a handy method of detecting the presence of resin in the size of a paper would aid in indicating its photographic value. Recently such a method has been described by Herr T. Morawski, and, as it necessitates the employment of no material of unlikely occurrence in a photographer's laboratory, we may here describe it. The paper is warmed gently with about a drachm of glacial acetic acid in a dry test tube, and, after cooling, a drop of concentrated sulphuric acid is allowed to flow down the sides of the tube; as the liquids mix, a colouration varying from bright red to violet indicates the presence of pine resin—the ordinary resin of commerce—in the sizing.

ONE of the strange turns in the wheel is shown in the employment of Rives so largely as is now the case. A quarter of a century or less ago we imagine that for one ream of Rives put on the market there were a score or more of Saxe sold, but at the present time the latter would seem almost to have died out of use. We are speaking of albumenised paper, and we are led to the belief through having observed the brands in use at many studios, and in no instance did we come across a single sheet of Saxe.

SPEAKING of scientific photographs, we should recommend as a capital subject for a popular *carte* at the present time a series of photo-micrographs of the British mosquitoes, several of which are permanent residents in this country. A short time ago a lively discussion was being carried on in the London papers upon this subject, the originating cause being a letter from an experienced traveller that he had seen and been bitten by real genuine mosquitoes on the banks of the Thames. After a series of letters had appeared the discussion was ended by the assertion of the common existence of English mosquitoes for many years back.

AT the last meeting of the Meteorological Society a large number of photographs of lightning flashes, taken during the storm of June 6, were exhibited, and excited much interest. They were over forty in number, and comprised a most varied series: there were the more ordinary, sinuous, meandering, and ribbon flashes, and, in addition,

pictures of knotted, multiple, and dark flashes. It is evident that photography will play an important part in elucidating the still abstruse mysteries surrounding the birth, life, and death of a "stroke of lightning."

A VERY interesting paper upon the effect of the absorption of ozone and of oxygen upon the solar rays was read at the last meeting of the Royal Society by Professors Liveing and Dewar, and in it they showed, under the effect of pressure, the presence of absorption bands in what used to be considered the specially photographic part of the spectrum. These bands had never before been observed the authors believed, and record was secured by means of photography. In another direction, on the Continent, M. Janssen had also been observing the absorption upon the luminous rays, but his chief difficulty was the supply of a sufficiently strong light through a long distance of air. Fortunately this difficulty has been overcome by the erection of the Eiffel Tower, which is about seven thousand seven hundred metres away from Meudon, and this in thickness represents approximately the thickness of an atmosphere having the same weight as the air surrounding our earth, and of density uniform and equal to that of the atmospheric stratum between sun and observer. By using a collecting lens, M. Janssen is able to obtain an intensity of illumination comparable to the sun's, and we may expect some very interesting results from the experiments and investigations he will make upon the absorption of the rays from the Eiffel lights in passing through six or seven miles of air.

THE PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

The following official circular has been issued:—

"LONDON MEETING, 1889, ST. JAMES'S GREAT HALL,
"PICCADILLY, W.

"DEAR SIR,—The Fourth Annual Convention of Professional and Amateur Photographers will be held in London, at the above hall, on August 19th to 24th inclusive. The proceedings, which will be opened by a conversazione, will include papers by eminent authorities, excursions, and lantern displays. An exhibition will be held daily of the latest and most improved apparatus, materials, and accessories; also photographs by eminent workers, as well as a separate exhibition of coloured pictures, on or from photographic bases, a new feature calculated to be of much interest. Large and influential local committees have charge of the Exhibition, Entertainment, and Excursions Departments. There will also be a collection of articles and works illustrating the history of photography. Programmes of excursions, with full details, and a list of convenient hotels, with their tariffs, will be forwarded to each member. The annual subscription is 5s.; a ticket of membership passes the holder to all meetings in the hall during Convention week. Members who desire to read papers or give demonstrations are requested to forward their names at once. Those who desire to exhibit apparatus or pictures will find conditions, regulations, and application forms accompanying this circular. The notable yearly increase in the number of members since the first Convention was held, the amount of good work done, the pleasure experienced by members, and the evident advantages arising from friendly intercourse between photographers from every quarter of the kingdom, lead to the conclusion that there is a vast future for the Convention. City and country, professional and amateur, art and science, dealer and customer, have here an unique opportunity of meeting and exchanging ideas, and the advantages of these Conventions have been not only theoretically argued, but practically felt and acknowledged. On account of the size, situation, and suitability of the hall acquired for this year, and as a commemoration of the JUBILEE YEAR OF PHOTOGRAPHY, the Convention of 1889 will, it is confidently expected, be a memorable event in the annals of photography. I trust, therefore, that you will support the Convention, and enhance its utility by your presence as a member. The names of those renowned in their various fields who have expressed their interest by becoming patrons of this year's Convention are a guarantee of the position the Convention now occupies in the worlds of science and art.—I am, yours faithfully, J. J. BRIGNSHAW, Hon. Sec."

The local Committee is a powerful and representative one, and with the London members of the Council are at present holding weekly

meetings to further the work in hand. The "Patrons" embrace the names of the highest dignitaries in the Church, the world of science and the world of art.

THE WHOLE ART OF PHOTOGRAPHY IN A SERIES OF EASY PROGRESSIVE LESSONS.

CHAP. VI.—THE INTENSIFICATION OF THIN NEGATIVES.

WHEN a beginner first tries his hand at developing a negative it is rarely, if ever, that he makes it right at the first, or even the second attempt. The most common fault is giving too long an exposure in the camera, and this is discoverable from the following symptoms: When the developer is poured over the plate, now lying on the bottom of a tray of suitable size, and is made to flow in an undulating fashion over the surface, *something* soon appears. Let us assume the subject to have been a house with trees and a sky. First of all, the portion representing the sky will begin to darken and show the outlines of the trees and house. But these quickly get merged into the sky, and all hope of making anything good of that negative must depart. It is over exposed, and, if washed and fixed, would only show a faint, ghostly image.

It is a characteristic of all over exposures that the images are thin and poor, but there are degrees in this fault, and when it is present to only a slight extent it is possible to render the negative sufficiently intense to yield a good print.

If the image is moderately bright, although thin, then is it possible to impart intensity to it; but if it be much veiled in the deep shadows, it is better to remove such veil previous to proceeding with the intensification. The principle on which this reduction of the image takes place is the application of a solvent, which acts slowly and uniformly, permitting of careful watching while the operation goes on, and of its action being immediately checked when once it is found to have proceeded sufficiently far. Of such reducing agents several could be enumerated, but of all these, a solution of iodine in cyanide of potassium for collodion, and a solution of ferridecyanide of potassium (red prussiate) with hyposulphite of soda for gelatine, possess special advantages. As we are at present speaking of the reduction of gelatine negatives, it is the latter that claims attention.

If a negative were placed into or had poured over it a solution of the ferridecyanide, the image would in a few seconds or minutes, according to strength of the solution, be converted into the ferro-cyanide of silver, which, being soluble in hyposulphite of soda, would ensure its total removal if plunged in a solution of that salt. But such a course would be attended with the disadvantage of the operator not being able to see how far to proceed with the prussiate. Hence it is desirable that the reducing bath consist of both of these agents, so that both actions proceed simultaneously, thus rendering the reducing action easy to be observed. The proportions first given by Mr. Howard Farmer for this purpose cannot be improved upon. The formula stands thus:—

A.	
Ferridecyanide of potassium	1 ounce.
Water	1 pint.
B.	
Hyposulphite of soda	1 ounce.
Water	1 pint.

To enough of B to cover the negative when laid in a dish add a few drops of A. Reduction commences immediately, and proceeds slowly. It is better to have but little of A present, else will reduction take place with too great a degree of rapidity. The action should be stopped when the deepest shadow in the picture begins to show as clear glass, after which the negative is subjected to a good washing. It will now be clear and bright, but too thin to yield a print. The mixed solutions should be thrown away, for although A and B will keep indefinitely when alone, they will not do so after having been mixed.

Next pour over the negative, or place it in a bath of a saturated solution of bichloride of mercury. This in a few minutes will cause a whitening of the image, the progress of which may be ascertained by raising the plate and examining the image through the glass. When the whitening has been effected, wash the plate so as to ensure

the total removal of the mercury, as any left in the film would cause stains in the next operation.

This white image can be converted into a dark one by several reagents, diluted ammonia being that most usually employed. Hypo-sulphite of soda, too, answers well, so does sulphite of soda. If the image be very thin, or it may be found desirable to impart more than the usual density to it, a solution of cyanide of silver dissolved in cyanide of potassium will be found most useful. To prepare this, pour into a twelve or fifteen-grain solution of nitrate of silver a rather weaker solution of cyanide of potassium, by which a dense precipitate will at first be thrown down, but which will be again dissolved by continuing the addition of cyanide.

The application of this to an image that has been whitened by mercury produces great intensity. There are other methods of imparting density to a feeble negative, but that just described will suffice for the present.

ECHOES.

THE idea of toning by a brush, spoken of in a leading article in last number of this JOURNAL, was, if I recollect aright, originally noticed publicly in 1862 by Mr. Heywood in the course of a communication to the Chorlton Photographic Society. It certainly is susceptible of being made useful by those who do not care to use expensive solutions in a lavish manner, and I think it would prove of exceptional value in such a process as that of Mr. Valentine Blanchard, in which a platinum salt is employed. But why not extend the idea? The localising of chemical action is a valuable adjunct to practice, and the application of a few drops of liquid here, there, or anywhere else on the surface of a negative, is undoubtedly conducive to effect, such being applied with a determinate aim. Is one portion of a negative weak? then apply by the brush the particular thing—call it intensifier, if you will—by which force is imparted, and so on, even to the application of local reduction.

Appropos of the imperfect fixing of the image by leaving in the substance of the gelatine or paper the double salt formed by the action of hyposulphite of soda on the haloid silver salts, the application of very hot water used to be considered a good test for the presence of such double salt. In prints, for example, if a stream of hot water were projected upon a print believed to be fixed and no change took place in its purity, except the slight lowering of tone almost inevitable upon the application of such a test, then was the print considered well fixed and its permanence might be relied upon. But if hyposulphite of silver were present—that intensely sweet-tasting compound with which experienced photographers are well acquainted—then does the hot water manifest the presence of the out-of-place compound by turning it yellow. Moral: Fix both negatives and prints well, so as to leave none of this compound in them.

Most willingly do I grant Herr Miethe the sole and uncontrolled use of such terms as "Anastigmatic Distortion," if he in return gives us the chance of obtaining his new lens, which he states embraces an angle more than most of us want, showing the edge and the centre of the field with equal sharpness, even with full aperture. If this equalisation of sharpness is on a flat plate, then results a positive gain over any other lens that I, at any rate, have yet seen. Think of an angle of 50° with an aperture of $f-6.5$, or of one of 90° with a small stop—and this with a non-distorting lens! or of a single landscape lens including a sharply defined field of 100° ! When, oh, when, are we to see in this country lenses possessing such capabilities?

Cock-a-doodle-doo! "We have," says L. H. Laudy to the amateur photographers of New York, "the best and cheapest farm implements, fire engines, firearms, fastest steamers, and best railroads, telegraph, photography, anaesthesia, sewing machines, electric light, telephone, phonograph, and, last, flexible films." We Americans, of course, were the discoverers or inventors of fire engines, firearms, steamers, anaesthesia, electric light, and photography. How long—how many years—does Mr. Laudy think was gelatine or collodion photography in daily use in this country before our good friends and brethren of the United States would even condescend to look at it? Is Mr. Laudy aware that the very man he eulogises as having made the first successful Daguerreotype portrait, and whom he calls "our

own countryman, Dr. Draper," was an Englishman, born near Liverpool, England? Is he aware that in firearms the superiority of the English is acknowledged so thoroughly in the United States at this very moment that nothing in this form is allowed to pass the Customs there without being mulcted in a heavy fine in shape of a protective tariff? Does he know how few are the years that have elapsed since the family that counts one of their number as the inventor of the telephone emigrated from this country to America? and lastly, is he aware that the inventor of the application of flexible films to photography, Mr. Carbutt, is an Englishman? For shame, to arouse national prejudices and antipathies among men who are, and who, with few exceptions, count themselves as brethren. There is, or ought to be, no nationality in science. How easily could I retort; but I won't follow Mr. Laudy's lead. JUNIUS.

LIGHTING THE SITTER.

III.

IN this article we propose to consider practically the effect of horizontal light upon the eyes of a sitter, with especial reference to reflections. We may assume, as an axiom, that a properly lighted portrait will show the pupil of each eye as a black spot, and that the cornea will be clearly defined in a considerable portion of its extent. The surroundings of a sitter, or the walls of a studio, may be divided into definite light and dark portions, which will be arranged in different ways, according to the direction in which the eyes are looking; thus the arrangement of blinds and reflectors adopted when the sitter is looking at the camera is different to that desirable when looking away from the camera.

We are not at present considering the skylight, but simply the side-light, together with the walls of the studio, which are very important in connexion with the proper rendering of the eyes in a photograph. In order to reduce our theoretical reasoning to practical fact, we may apply to a modern type of studio the rules which are easily deducible from a consideration of the laws of reflection.

If we refer to our diagram, where *s* is the sitter and *m* the camera, we have, in the ordinary studio, the wall behind the sitter occupied by the background. There is a large side-light or casement at *p*, with a skylight above it; all the rest of the studio wall is usually built solid—i.e., without windows. In order to prevent the cast shadows being too harsh it is customary to paper the whole of the walls—*A*, *B*, *Q*, and *X*—with a white or very light material. The large window at *p* is generally furnished with blinds or curtains to alter or subdue the lighting, and there is usually in the studio a moveable frame, covered with white material, which acts as a reflector to give additional softness, when required, to the shadows on the face of the sitter.

Now in such a studio a person can undoubtedly be photographed after a fashion, and a recognisable portrait secured, but the eyes will be indistinct, especially in the case of blue eyes. The effect of light falling from all directions on the shiny eyeball is to have the whole area blurred by reflected light, precisely as if it were viewed through a bit of fog or mist which existed only over the eye. By having certain portions of the studio wall made dark we can remove this fog entirely.

We will commence with the wall behind the camera, which may be permanently covered with a dark material up to a height of about eight feet from the floor. In a double-ended studio this may be, and is, generally accomplished by having a background hung there. This background should preferably be a dark one if the studio is short. In the case of a long narrow studio, where the casement and skylight is some distance from the wall behind the camera, the necessity of a dark or non-actinic paper is less pronounced, as this wall will probably be in shadow deep enough to prevent an injurious quantity of light being reflected. But in a short studio the wall behind the camera should be of a decidedly dark or non-actinic character, it being a good rule that no light should proceed from the space near the camera.

With regard to the side walls, we may either have them wholly papered with a dark or non-actinic material, and have white blinds to draw down over them when reflected light is wanted, or we can adopt the plan of white-papered walls, having dark blinds of any suitable colour, green or brown for instance, to cut off injurious

light. Probably the first method is the best, as very often the white blinds will not be needed at all, the moveable reflector taking their place.

We will accordingly assume that the entire wall of the studio is repapered with a tint that will photograph dark, it may be a light yellow or orange, but a dark blue or grey would enable one better to judge of the lighting. With a paper of an orange tint, the shadowed side of the face would be lit with non-actinic light, and would appear much darker in the photograph than one might expect from the appearance of the sitter.

If our studio is narrow, a white blind may be hung on a roller to cover the wall at A. Another may also be put at n on the casement side; but this will be seldom required. As q is a wide space, it would require a very large blind to cover it, so it will be better sometimes to use the small moveable blind or reflector, which can be placed nearer to the sitter with its edge towards the camera. This reflector will answer quite as well as the large blind at q in the case of a single figure, though with a group the reflector would have to be larger and at a greater distance from the sitters in order to prevent it being in the way, so that with the group it might be convenient to have two white blinds to cover the q wall.

With a large studio, the q blind need not extend to the back corners of the studio. It may be hung at an angle with the wall and some distance in front of it, so that the edge is turned towards the place where the camera would be when photographing a group. Spring rollers are the handiest, fixed seven or eight feet above the floor, so that the white blinds can be drawn down to any extent by a pull with the hand. Two such blinds placed in a line would give a total white surface of seven or eight feet square, which would form a reflector large enough for any ordinary studio group. When single figures are being taken, these large blinds can be rolled or sprung up out of the way, and the smaller moveable reflector used instead at a shorter distance from the sitter.

If the studio is wide, say over ten feet, the blind at A may be similarly hung parallel to, and some distance in front of the wall, instead of being close to it; the advantage of this is that a smaller blind can be used. The efficiency of a reflector depends upon the distance; a white sheet, three feet square, placed a yard from the sitter will reflect as much light on his face as a sheet six feet square would if placed at two yards distance.

Thus we have now papered the inner walls of our ideal studio with dark paper; we have arranged a white blind at A, and a larger blind or pair of white blinds at q; we have also a moveable white reflector, which may be three or four feet square for use with small subjects—half-length figures, bust portraits, etc. Now for the adjustment of this apparatus.

If the sitter is looking at or near to the camera, which is assumed in all cases to be equidistant from the sides of the studio, we find that A, n, and x must be dark in order to preserve the pupil and the whites of the eye from reflections when viewed from the camera. As x has been made permanently dark, we need not consider this point; n being occupied by the casement, it is evident that the reflector must be at q, so either the large blinds at q can be drawn down to the desired extent or the small moveable reflector used instead, it being put in a position midway between the sitter and q, with its edge turned towards the camera. This general arrangement is to be followed with all sitters when the sight is directed to the camera.

Of course it is not necessary to use always the whole of the light coming through the ground or fluted glass of the casement, or to employ the full power of the reflectors by having them completely drawn down. These matters will vary with the individuality of the sitter and the artistic taste of the operator.

In the case of a group, it is desirable, in most cases, that the sitters should look in different directions; hence we cannot ask them all to look at the camera. We may direct one to look at the lens, another at a point two feet to the right of the camera, a third two feet to the left, a fourth may look out of the casement, a fifth at the middle of the reflector; in fact, when the blinds at q only are in use, the point of sight may be anywhere except near to the corners of the studio behind the camera, so that it must not be imagined that our rules admit of no variation of treatment.

Let us now consider another case. Probably the most popular position of the photographic face is the partial profile; the far cheek being in shadow serves as a dark background to the nose, while both eyes are visible. This position of the face naturally causes the eyes to look into the corner of the studio behind the camera. To avoid reflections, we find that this direction of the eyesight requires that q and x should be dark. It is now that the reflector at A is wanted; the blinds at q should be rolled up quite away. If the moveable reflector is placed

between the sitter and A it will answer the same purpose as the larger blind in the case of single figures, which will permit it to be placed at a comparatively short distance from the face.

In the case of a group, with merely the A reflector in use, we may direct the sitters to look at any point, except near to the camera and near to the middle of q. Thus one person may look at the corner of the studio behind the camera opposite the casement, another may look at the casement, others, with good profile features, may look at A or B.

When photographing a group it is unwise, to have both the reflectors, A and q, in use at the same time, as then we should be obliged to turn every face to A and n, or towards the casement, which would scarcely be desirable, except in a line of soldiers at drill, or some other unusual subject.

If circumstances—insufficient daylight, for example—demand such an amount of reflected light on a group that both A and q blinds must be used, we can make the best of the situation by directing the light or blue eyes to look out of the side window, while the darker eyes may look in other directions; but this device does not always give a satisfactory result, and should be regarded as a makeshift one.

ALBERT WM. SCOTT.

(To be continued.)

COLOURED PHOTOGRAPHS.—I.

It is usual for the artist of uncertain grade to look with contempt and scorn upon those products which form the subject of these papers. When they are asked by the ignorant to give an opinion upon some coloured works which may have photographic bases, they sum up with the simple remark, "They are after all" (however good) "*only coloured photographs*." Of course there are also artists, of whose grade or position there is no doubt or uncertainty, who appreciate the help and general usefulness of photography. The most I wish to express as my own opinion is, that I see no reason why a real artist should fail to produce a most meritorious and thoroughly artistic result upon a photographic base. In other words, to take portraiture, I see no reason why a photographic enlargement, painted, should not hang beside a painting pure and simple, and hold its own as regards style and treatment. Of course, to achieve such a result, knowledge must be the keystone of the work.

In these papers I will try to give the best means for acquiring a thorough knowledge of photographic colouring as practised by some of the most successful artists whom I have met during the past twenty years or so. And although I may not say distinctly whether the theories advanced are my own or those of friends, I of course shall not hesitate to take the responsibility that must naturally attach to my writings on the subject.

To many who have not the taste and perseverance necessary to acquire a thorough use of the brush, as well as a keen appreciation of the numerous, I might almost say inexhaustible, delicacies of colour, and who, at the same time, do not look down upon the common thing—a coloured photograph—photography may still be their friend. Every one has heard of photography in *natural colours*. Indeed, I think there are many who wish they never did hear of it; but this is purely a matter of taste, and may be traced more to the money lost, perhaps, than to any wear and tear to the brain in struggling to attain so desirable an object. To the votaries of *photography in natural colours* I can give one little advice—be patient. The more patient the reader is, and the longer he lives, the more likely he is to see the result so dear to him at last realised. He should pay greater attention to the latter condition than may appear at first necessary, but if things go on as they do at present, I think it will be more than a year or two before we can, with safety, consider photography in natural colours as an accomplished fact.

We are told, in some place or other, that we should be thankful for small mercies; but to photography the ordinary common or garden artist should be more thankful still. There are many who possess a keen appreciation for colour, and can apply the same with a delicacy and feeling truly artistic, but who are not at all worthy to be considered draughtsmen. To such as these what a boon photography must be! Photography supplies them not alone with an outline such as the most skilful draughtsman could scarcely hope to produce, but also all the delicate effects of light and shade are also secured. This being so, I maintain that a good man can produce a highly artistic work.

The basis of all art must necessarily be *form*; there are many cases, however, in portraiture where colour is almost as indispensable to render the likeness a striking one. There is not, in my mind, any class

of painting which gives such play to an artist's intelligence and sense of feeling as does portraiture. This may be readily seen by inspecting the works of our many great portrait painters. One will possess the gift that enables him to give life and expression (no matter what the style of work), while another will fail in these qualities, notwithstanding that his colouring may be good and his manipulation without any very particular fault. The power to impart life and vitality to a portrait I do not believe to be (if I may use the term) acquired. It must be born in the artist. There is something almost magic in the touch which can give life and intellect to a head. In a lesser degree an operator may possess this quality when photographing. I know photographers (good ones) who pose heads; they are good, so to say, and like the people, but they do not look *alive*, they lack "go," while others with the slightest turn of the head, be it up or down, more this side or that, it matters not, but they impart importance as a picture, and life-like resemblance as a portrait.

It is needless to say that when we try to get the very best effects in coloured photographs we should consider that all efforts, both on the part of the photographer as well as the painter, must be exerted to the fullest. They must work in union of sentiment, although they may not have the least connexion in business, and perhaps be even strangers to each other. If each be endowed with that artistic feeling which is so essential in the production of successful portraiture, when the photographer's work is placed upon the painter's easel there will be a kind of magnetism which the latter will feel, and which will enable him to carry out the portrait to a successful completion.

From the foregoing it may be gleaned that my remarks will be wholly applicable to portraiture. It will be well to bear this in mind, as many of the conditions laid down would not equally apply to the other branches of photographic colouring.

A portrait—to be worthy of a name, as well as to possess artistic merit—must have one great quality; it *must be natural*. By this I do not wish to infer that when it is *natural* it will necessarily be a portrait. Nature, in many of her aspects, is anything but beautiful, and it would be highly inartistic, not to say absolutely stupid, to depict the same on canvas, while we can, by a little care and study, select others that will show her to better advantage. The truth of this will be evident if we study some of the many examples of instantaneous photography. I have seen photographs of horses in positions, the most absurd positions, in fact, that it would be sheer madness to paint them in; yet they are *natural* all the same. As it is with horses so, too, is it with man. We have our stupid and absurd positions, and it would be folly to secure them in a portrait. There is a good deal of the brute about us men, and at times no small amount of the ugly. Would any of us like these qualities forced into prominence by an artist in a picture? I think I can safely say "we would not." I will also say that, putting aside our vanity (please excuse the pronoun), we are justified, on sound and artistic grounds, in objecting to such a treatment. Where beauty can be found it should be sought after, and where nothing but ugliness might exist its least repulsive form should be selected.

Man, under the many and ever-changing effects of light and shade, is by no means an easy subject to treat—artistically, I mean. All may be natural, but no artist would select them for a picture. Successful *portrait painting* (and the same refers to the photographer operating) is not accomplished by simply securing on canvas or paper a copy of what is undoubtedly natural. Intellect and beauty must receive the artist's best attention. It is this natural ability—in a painter or photographic operator to secure grace and beauty in the posing of his subjects—that gives its possessor an undoubted advantage over his less gifted fellow-workers. The point to be attained, then, by every true artist, or artistic photographer, is to portray nature under such favourable circumstances as will do justice to the intellectual character of the model, and at the same time invest it with the necessary amount of pleasing pictorial effect.

In this regard the painter has a very marked and appreciable advantage over the photographer, namely, *colour*. By judicious and skilful colouring a defective or offensive feature may be made to escape the eye of an ordinary observer, while the photographer, with his *monotint*, is more or less helpless, unless as far as the retoucher can aid him on the negative, and a further working up upon the print. But even all this may fail to hide the defect in the photograph, while, in the painting, *colour* will work like magic.

To obtain a really successful portrait is anything but easy to either the painter or the photographer. Indeed, it says much for the ability and artistic knowledge of many of our leading operators the rapidity with which they pose and despatch a sitter, yet secure a characteristic portrait. This, too, when some of our most illustrious artists seem to have needed as many as fifty sittings for a portrait. What a help a good and successful photographer would have been to such men,

The hours upon hours that might be saved both to artist and sitter!

Many times I have reflected upon the help that photography gives to an artist and the time it saves him. At the same time I believe it helps a really good artist comparatively more than it does the lesser lights. In this category I do not include artists who would be more correctly styled colourists.

In the question of *expression*, the artist has considerable advantage over the photographer. The sitter being absolutely free to do as he pleases, the painter may be able to catch the desired expression in the heat of conversation. He will catch that flash of intellectual expression which gives life to the picture and is the spirit, as it were, of the portrait. The photographer, on the contrary, when he is about to take the picture, whatever animation may have characterised the sitter before is subdued, if not altogether ruined, by the fatal "I am ready now—steady, please!" The mild suggestion to "look pleasant" seldom has the desired effect, and the sitter is as likely as not to put on an expression the like of which he may never before have displayed. This, needless to say, does not form a likely basis for a successful portrait. This, in many cases, the operator knows, and although he exposes the plate, feels sure it will be wasted.

There are many photographers who give no care to the study of the artistic bearings of a portrait, and leave chance to decide whether the portrait will succeed or not. A very usual cry, too, is, "Oh, the retoucher will put that right." Of course, this may or may not be so, and must necessarily depend upon the artistic training of the retoucher in question. I have known cases where a happy accident has been the means of gaining a successful picture; but this means of arriving at successful portraiture I cannot recommend as a good system to be followed.

I am glad to be able to state that many of our leading artists have done lately what they should have done years ago—taken up photography. I have not the least doubt but some sound good will come of it and an improvement be felt in photographic portraiture generally. Our efforts, therefore, must be directed with an eye on both sides, as our object must be to produce successful coloured photographs.

REMOND BARRETT.

THE ADAPTABILITY OF VARIOUS PRINTING PROCESSES, AND SOME REMARKS ON AN OLD PROCESS REVIVED.

[Camera Club.]

MANY amateur photographers seem to hold very decided views on the subject of printing, and we frequently hear condemnation of this or that particular method according as the tastes or fancies of individuals differ. I think, however, that if we take each process in turn and give it a fair trial we shall find that there are certain circumstances under which we shall do infinitely better and obtain more satisfactory results from negatives hitherto deemed incapable of printing artistic pictures than if we had adhered to our favourite method of procedure.

The means by which images from the negative can be produced are so many and various that it would be quite out of place to attempt to introduce them here, and I will, therefore, confine myself to those well-known methods more familiar to photographers of the present day. Foremost amongst these is, undoubtedly, the old silver albumen process, and, in spite of all that has been said against it, it seems yet to hold its own against them all. We sometimes hear that its days are numbered, and that silver albumen must sooner or later give place to one of its more modern competitors; but if we consider a moment I think we shall come to the conclusion that until the professional gives it the cold shoulder, or some less troublesome and cheaper printing-out process is discovered, silver printing has a long life before it. Certainly the mass of professional photographers, both in London and the provinces, although they occasionally have a platinotype or bromide print in their cases, show no inclination to abandon silver albumen. Much has been said about the want of permanence, but I have here over two hundred prints mounted with starch that have stood the test of twenty-five and thirty years in a London atmosphere without showing signs of deterioration, except in one or two cases where the hypo has not been effectually removed. For high-class portraiture on a large scale the palm must be yielded to one of the platinotype or mechanical processes: but the advantages of the old process are cheapness, softness, good detail, and variety of tone; the disadvantages—difficulty in keeping, owing to the decomposition of the albumen, want of latitude, and in many cases rapid fading of the image when continuously exposed to the light.

The next best known is probably the Eastman, and some very fine

effects have been obtained with this paper; opinions, however, vary so much with regard to the merits of the bromide and platinotype papers, and are in many cases so distinct and so decided, that it must be understood I am merely giving what experience I have gained on this head with due reserve. This paper I have found very reliable, giving fairly good results, but not suitable (in common with other bromide papers) for small work; its greatest charm is the large latitude which it allows, and it will give good results with the thinnest possible negatives, which would be useless with any other process. This consideration makes this paper very useful to that body of amateurs who are bold enough to admit that under certain conditions they have a sneaking liking for "rule of thumb;" and we have yet to learn that the "solution men," with all the paraphernalia of actinometers, view-finders, and algebraical formulae, are much ahead, or spoil less negatives, when quickness, skill, and judgment are necessary, as in instantaneous work. The objection to the bromide papers is, however, the development, which, from its troublesome nature and the length of time employed in the clearing, fixing, and washing, places it out of the race as the paper of the future.

A nearer approach to the great desideratum are the platinotype papers, especially the Pizzighelli, which in simplicity, and, presumably, in permanence, should leave nothing to be desired. It is, however, as yet on its trial, and it remains to be seen if any of the papers which require a medium—albumen, gelatine, or arrowroot—will be equal to those in which the image is incorporated in the fibre of the paper itself. The process of Mr. Blanchard seems in this particular (i.e., the direct deposition of the image in platinum or silver) to be a step in the right direction, the only objections being the necessity of fixing in the usual way and the addition of silver.

About 1840 Sir John Herschel invented what is now known as the cyanotype process; that abnormal salt, the ammonio-citrate of iron, probably owes its sensitiveness to the action of the organic acid. Kept in solution with ferri-cyanide of potassium, it in time throws down a Prussian-blue precipitate, even when kept in a dark place; but when exposed to direct daylight its action is almost as quick as the ordinary silver albumen. A nearly saturated solution is spread with a brush on damp paper and exposed in the ordinary printing frame, after drying, until the image appears. This is generally treated with a solution of ferri-cyanide of potassium, the result being a vigorous image of a bright blue colour. To obtain clear whites the paper must be used shortly after preparation or decomposition of the salt sets in. It must, for the same reason, be kept in a dry place. Treated with a neutral chloride of gold a brown or purple image results, growing gradually darker as the treatment is prolonged. Ferri-cyanide of potassium (yellow prussiate of potash) appears to give a positive picture. Nitrate of silver is also reduced in the usual way, and some of the baser metallic salts are also affected. Platinum I have not tried, but it seems to me that the ammonio-citrate of iron has been neglected in its capacity as a reducing agent for the higher metals, the preparation of the paper being so simple, the cost so small, and the field for experiment so wide.

I trust you will pardon the shortness of this paper, as my object has been more to raise discussion on this interesting subject, in the hope that some one may take it up with a view towards the discovery of a simple and direct printing-out process, than to call your attention to matters and methods of procedure so familiar to you.

ERNEST SEYD.

UNIVERSAL FORMULA FOR CALCULATING EXPOSURES FOR ENLARGING AND REDUCING.

(Camera Club.)

ANY formula which will reduce exposure to practical certainty is welcome. The author of this paper has worked out a formula for finding the correct exposure for enlarging and reducing which is simple to use. Necessity led to the calculation, for it appears that no such formula exists. The writer is indebted to Professor Fleming for suggesting a modification which simplifies the result:—

Let I = the area of image (i.e., the sensitised paper or plate).

O = the area of object (i.e., the negative).

F = focal length, or conjugate, measured from O to the optical centre of lens in inches.

f = solar focus of the lens in inches.

K = a constant multiplier, to make up for loss of light in passing through the medium (if any) placed between the light and negative, and in passing through the lens.

C = contact exposure in seconds, supposing that the medium (if any) placed between the light and negative is removed,

and the sensitised paper or plate is placed in contact with the negative, all other conditions remaining the same. (It is evident that, by regulating the quantity of light and varying its distance from the negative, C may be made any value, and can be easily determined by experiment.)

e = required exposure in seconds.

E = required exposure in minutes.

S = diameter of stop employed in inches.

n = number of diameters of I contained in diameter of O.

Now consider the following diagram, which speaks for itself:—

Let light fall on O, and confine our attention to a point of light at A; this ray, on passing, spreads out in all directions, and only a cone of these rays passes the lens limited by the size of S. The relation between the whole of the rays and this cone may be thus expressed: Suppose a hemisphere to exist on the lens side of O, with A as centre and F as radius, then it is evident that—

$$\frac{\text{Whole of light}}{\text{Light passing lens}} = \frac{\text{Surface of hemisphere}}{\text{Portion of surface of hemisphere bounded by stop aperture.}}$$

The numerator = $2\pi F^2$, and the denominator = $\pi(\frac{1}{2}S)^2$ (for the area of the stop aperture and the portion of the hemisphere limited by the aperture of the stop are virtually the same, the area being small).

Thus we may express the above relation by—

$$\frac{2\pi F^2}{\pi(\frac{1}{2}S)^2} = \frac{8F^2}{S^2}$$

This is one of the exposure factors, because the smaller is S the larger the fracture becomes, and consequently increased exposure.

The other factor is $\frac{I}{O}$, for the exposure will vary in this ratio; hence—

$$\text{Exposure factors} = \frac{8F^2 I}{S^2 O}$$

Taking K and c into account—

$$e = 8KC \frac{F^2 I}{S^2 O} \text{ and } E = \frac{2KC F^2 I}{15 S^2 O}$$

Since $\frac{O}{I} = n^2$, $\therefore \frac{I}{O} = \frac{1}{n^2}$; and, as well known, $F = (n+1)f$, $\therefore e = 8KC \left\{ \frac{n+1}{n} \cdot \frac{f}{S} \right\}^2$

Let c be made 1 second, and K = 2, that is loss = 50 per cent., made up thus: say 10 to 15 per cent. for absorption and reflection of light in passing through the lens, and 30 to 40 per cent. for loss of light due to the ground glass or other material interposed between light and negative.

$$\text{Then } e = 16 \left\{ \frac{n+1}{n} \cdot \frac{f}{S} \right\}^2 = \left\{ 4 \cdot \frac{n+1}{n} \cdot \frac{f}{S} \right\}^2$$

To find E let $\frac{1}{2}$ be taken as 4, which is near enough for practice.

$$\text{Then } E = \left\{ \frac{1}{2} \cdot \frac{n+1}{n} \cdot \frac{f}{S} \right\}^2$$

This formula gives results in minutes, and is easy to apply as well as to remember.

Example.

A lantern plate has to be made from a whole-plate negative. Arrange matters so that C = 1 second. Everything being properly adjusted, find exposure in minutes; n may be taken as 3.

Let f = 8 inches, and S = $\frac{3}{4}$ inch.

Then $E = \left(\frac{1}{2} \cdot \frac{3+1}{3} \cdot \frac{8}{\frac{3}{4}} \right)^2 = \left(\frac{2}{3} \cdot \frac{32}{3} \right)^2 = \frac{64^2}{9^2}$; $\frac{64}{9}$ may be taken as

7 for a practical result.

Then exposure is 49 minutes.—ANSWER.

If c = 2, 3, &c., then the result must be multiplied by 2, 3, &c.

Note.—When condensers are employed with a powerful source of light C becomes a small fraction, $\frac{1}{7}$ or even $\frac{1}{10}$. The best way to proceed in such cases is the following: Obtain the correct exposure in seconds, for one case, by experiment, and let this be called e';

$$\text{Then } e' = 8KC \left\{ \frac{n+1}{n} \cdot \frac{f}{S} \right\}^2$$

In this method of working the loss by absorption may be taken as 20 per cent.

Thus $K=1.2$,

$$\text{and } e' = C \cdot 9.6 \left\{ \frac{n+1}{n} \cdot \frac{f}{S} \right\}^2$$

$$\text{and } C = \frac{e'}{9.6 \left\{ \frac{n}{n+1} \cdot \frac{S}{f} \right\}^2}$$

Since the values for e' , n , S , and f are known, a known value is found for C . This once found, C becomes a constant for the condenser and lamp with which the experiment was made. The density of the negative has to be taken into account, but if a medium negative be used for this experiment, very little judgment is required to make the necessary allowance. Or the values for C may be obtained with two or three negatives of varying densities, so as to eliminate "judgment" altogether.

Note.—In accordance with Mr. Elder's suggestion the further simplifications of the formulæ are now given.

For general work—

$$e = 8 KC \left\{ \frac{n+1}{n} \cdot R \right\}^2 \quad (I)$$

and for condenser—

$$e = 9.6 C \left\{ \frac{n+1}{n} \cdot R \right\}^2 \quad (II)$$

Thus the usual ratio numbers on the stops may be employed, and if these are marked on the decimal system, then let S = number on stop; and since $R = \sqrt{10S}$, and $10 \times 9.6 = \text{approx. } 100$ and $\sqrt{80} = \text{approx. } 9$, we obtain—

$$e = KCS \left\{ 9 \cdot \frac{n+1}{n} \right\}^2 \quad (I)$$

$$e = CS \left\{ 10 \cdot \frac{n+1}{n} \right\}^2 \quad (II)$$

SIR DAVID SALOMONS.

THROUGH JAPAN WITH A CAMERA.

CHAPTER V.—AWAMORI—LECTURE IN THEATRE—JAPANESE FEAST—GAISHA.

On the night of Saturday, August 8, we were conducted by our entertainers of Hakodate, each armed with a coloured paper lantern, to a police boat, in which we were rowed to a steamer to take us to Awamori, the northern town of the mainland. The steamer started at about midnight, and we arrived in Awamori at about eight o'clock on Sunday morning. Of Awamori itself I have nothing to say that would interest readers. It is a fishing village, not very picturesque, and smelling very badly of decomposed fish. All the time of the day and a half that we stayed there was spent on business, including a lecture delivered in the theatre.

A Japanese theatre is not, in general structure, very different from an English theatre with only one gallery, the front of which, however, is not curved, but is rectangular. There are no seats, of course, but the eternal straw mats. A "front row box," in the place corresponding to the dress circle, is simply a portion of the floor partitioned off on the two sides and the front with boards about nine inches high, the back being formed by the step (about the same height) which makes the difference of level of two tiers. Such a box will accommodate six Japanese, but only about two Europeans, as these latter are continually in trouble as to how to dispose of their legs. The stage has a large circle in the centre arranged to revolve, so that one "set piece" may be arranged at the back, and may, when it is desired, replace that in front by simply revolving the platform. The performance begins in the morning, and lasts till about eight or nine at night. The acting is often very good; but still, some six or eight hours of a Japanese theatre is as large a dose as a European can stand, spite of the tea and bits of food which are served at intervals, apparently not at any fixed times, but just when the attendant thinks that the playgoer looks hungry. In the better theatres no actresses perform; but female parts are impersonated with wonderful correctness by men. I was rather surprised, after seeing all that I have described, to hear that it is considered here improper for young women to act on the stage. Perhaps the person who told me so was chafing.

In Awamori the theatre was crowded—to "see a foreigner speak," I was told. It was a strange sight to look down into the pit. It was filled with a mass of squatting and sprawling humanity. A number of the people had brought out very young children (rather, I suppose, than leave them at home alone), and most of them lay sound asleep on the straw mats quite naked. The people who were awake were mostly smoking. Not that the smoking was confined to the pit; we, who were on the stage, also relieved the monotony by cigarettes.

After we had left the theatre we went to an entertainment given to us by the chief officials of the town, and as this entertainment was in true

Japanese style, something quite new to me, or rather new for the first time at Hakodate, and as it was typical of various other entertainments that we had, I describe it here in some detail.

We assembled in a large room on the first floor of what was, I believe, a private house—a very large room, perhaps about forty feet by twenty feet. There were about twelve or thirteen of us, and we sat on the floor in a circle at one end of the room, or, more strictly speaking, in a sort of horseshoe form, open towards the unoccupied end of the room. I had the place facing the empty end of the room. I don't know whether it was the place of honour or not. A thing that was much more to the point I do know; there was a post at my back, which made sitting on the floor for several hours possible.

A never-ceasing succession of little lacquered wooden bowls with various kinds of food in them were brought in. In front of each eater is placed a small square wooden tray, supported a few inches above the floor level on four short legs; on this are placed the lacquer bowls. The food consisted of soup of various kinds, seaweed entering largely into the composition of this; of fish, raw and also cooked in different ways; and of various dishes, as to the composition of which I am unable to hazard even a guess. There is often chicken, but seldom any other kind of flesh meat. All have to be eaten with chopsticks, a thing not very difficult if one is once taught the right way, very difficult indeed if one is not. One stick is held quite rigidly between the fork of the thumb and first fingers. The other is held between the point of the thumb and those of the first and second finger. If the reader likes to try them—say with a couple of pencils—he will find that he can pick up small articles with greater ease than might be supposed. After a little practice it is easy to pick up anything, from a pin to an orange.

Shortly after our supper had begun a number of Gaisha appeared on the scene. Gaisha are singing and dancing girls, and take a prominent part in all purely Japanese entertainments, the Japanese holding the truly Eastern notion (with which I considerably sympathised) that it is very foolish for a man to dance and sing himself when he can pay girls to do it for him. Gaisha are, naturally, selected for their profession greatly on account of their beauty, and it is probable that many of the prettiest faces to be seen in Japan will be found amongst the professional singers.

At the entertainment that I am writing about the Gaishas sat in an inner horseshoe facing the guests, and began at once to make themselves agreeable, talking pleasantly, and helping the saké.

Saké, the national drink, is a sort of wine somewhat resembling very thin sherry. It is generally drunk hot, and is far from unpleasant. It is drunk out of very small cups or bowls, and the drinking of it, when several Japanese are together, is accompanied with some ceremony. Thus, when one of my entertainers thought fit to honour me by drinking with me, he washed his own saké bowl in a small basin of water which was in front of him and handed it over to me. It was filled by one of the Gaisha, and I, washing out my own bowl, handed it back to be also filled.

When the food was done, or nearly so, most of the Gaishas took themselves off to the clear part of the room, and there played, sang, and danced. The instrument used for playing is the samisen. It is more like a three-stringed banjo than any other instrument I know of, and the amount of noise that a skilful player is able to extract from a samisen is astonishing. I must confess that I have been unable as yet, at any rate, to cultivate a taste for either samisen playing or Japanese singing. The samisen makes a loud and harsh sound, and the singing appears like a sort of lamentable wailing in a minor key.

The dancing is a few degrees better, although it is not dancing at all as we understand the word, but is a mixture of posturing and a sort of acting. Every dance tells a tale, I believe, and I am told that when one understands the tale told by the dancing and singing combined, it is all very amusing. I can believe this, for once being given the thread of the story contained in a dance I followed it with considerable pleasure, a good deal of histrionic talent being exhibited. Moreover, some of the attitudes are very graceful. Still, whilst fully appreciating the charm- ingness of the Gaisha, I always felt that they would be still more charming if they were to leave their samisen at home and confine themselves to flirting, an art in which they are great adepts.

W. K. BURTON.

ON ALLOTROPIC FORMS OF SILVER.*

SILVER is capable of existing in allotropic forms possessing qualities differing greatly from those of normal silver. There are three such forms, or rather modifications of one form, differing from each other in many respects, but all more nearly related to each other than any one of them to normal silver. One of these forms is soluble in water, passing readily to an insoluble form; and this last may, by the simple presence of a neutral substance exercising no chemical action upon it, recover its solubility. Another form closely resembles gold in its colour and lustre.

Whether metallic silver shall be reduced from its compounds in its normal or in an allotropic form depends upon the reducing agent employed, so that it cannot be said with any certainty whether it exists

* From the American Journal of Arts and Sciences.

in its compounds in its ordinary or in an allotropic condition; the latter alternative seems at least equally probable.

These allotropic forms of silver are broadly distinguished from normal silver by colour, by properties, and by chemical reactions. They not improbably represent a more active condition of silver, of which common or normal silver may be a polymerised form. Something analogous has already been observed with other metals—lead and copper.

Much having been written, especially within the last few years, on the products of reduction of silver compounds, a brief summary of what has appeared may be desirable before proceeding further. The study of this subject has led to remarkable divergencies of opinion on the part of the chemists engaged in it. Almost all the views advanced have been successively disproved by each subsequent publication. It follows that what has taken place in text-books is almost wholly incorrect.

The earliest experimental work was Faraday's, but his product has been proved to be a mixture. The next was the well-known paper of Wöhler published in 1839. It is not my purpose here to enter upon a criticism of this memoir. If this illustrious chemist succeeded in obtaining by the means employed a true citrate of silver hemioxide—as would appear from his analysis—no chemist since his time seems to have done so. The next publication to Wöhler's was that of Von Bibra, who used Wöhler's method, and whilst affirming that he obtained a similar citrate, found an entirely different constitution for the corresponding chloride; for instead of obtaining a hemichloride, Ag_2Cl , he gives, as the result of fifteen concordant analysis, the constitution of his product as Ag_2Cl_2 . A citrate to yield such a chloride (if such a chloride exists), by the simple action of hydrochloric acid, could scarcely have the constitution assigned to it by both Wöhler and Von Bibra.

In 1883 Pillitz published two papers. He commences by disputing the probability of the existence of Ag_2O , on grounds of valency; namely, as implying that oxygen may be quadrivalent. Although it is very doubtful that any one has up to the present time succeeded in obtaining Ag_2O , the argument seems futile, as are many arguments deduced from supposed laws of valency. Similar reasoning would make Ag_2Cl impossible, which substance undoubtedly exists, and it would also deny the existence of K_2Cl , which stands upon such authority as that of Rose, Kirchhoff, and Bunsen. Pillitz carefully examined the so-called hemioxide precipitated by alkaline solutions of antimony and tin and could find no trace of Ag_2O in any of them. He did not examine Wöhler's products.

The first person to deny categorically the existence of Wöhler's series of hemi-compounds appears to have been Dr. Spencer Newbury. In two interesting papers he describes a repetition of Wöhler's methods, and declares it to be impossible to obtain products of constant composition. The red solution taken by Wöhler to be argentous citrate Dr. Newbury concludes to be a suspension of finely divided silver. Muthmann, after a careful examination of Rantzenberg's products, concludes that that chemist was wholly in error in asserting the formation of compounds of chromic, molybdic, and tungstic acids with silver hemioxide. He next studies the red liquid obtained by Wöhler's process, and comes to the same conclusion as Newbury, that it consists of finely divided silver suspended in water. I shall not dispute the correctness of this opinion in the case of the liquid examined by these two chemists; at the same time I cannot accept the tests of solution employed by Muthmann. That a substance will not pass through a dialyser shows that it is colloidal, and is no proof whatever that it is not in solution. Animal charcoal takes up many substances from true solutions. Decolourisation by animal charcoal is no proof whatever that the colour removed was not in true solution. By freezing, the molecular condition of a substance may be changed. Muthmann found that when the red liquid was mixed with gum-water and precipitated with alcohol the precipitated gum carried down with it the red substance, thence deducing that it was only in suspension. A solution of litmus was mixed with gum-water and precipitated by alcohol, the mass of the litmus went down with the gum, a trace only appearing in the filtrate. With Hoffmann's violet the same result. Yet no one, I think, will assert that these two substances do not make true solutions in water. Even, however, if these arguments could be admitted, they would not apply to the solutions presently to be described, which can be proved by optical means to be true solutions. I propose presently to show that silver may exist in a perfectly soluble form, dissolving easily and abundantly in water. Starting from this, it may show all degrees of solubility down to absolute insolubility; still, however, existing in an allotropic form and quite distinct from normal or ordinary silver. The solutions formed are as perfect as those of any other soluble substance.

Wöhler's process was next repeated by G. H. Bailey and G. J. Foster, who came to the conclusion that no citrate of hemioxide was formed, and that Wöhler's results must be neglected.

Von der Pfordten endeavoured to obtain hemi-compounds of silver by acting on the nitrates with an alkaline solution of sodium tartrate, and also with phosphorous acid. His determinations were made volumetrically, based on an opinion that a permanganate solution acidified with sulphuric acid would dissolve silver hemioxide but not metallic silver. Previously to receiving his paper I had found that sulphuric acid, even when diluted with ten times its bulk of water, was capable of acting upon finely divided normal silver and of dissolving an easily recognisable quantity.

Von der Pfordten's conclusions were thus vitiated entirely. It should, however, be remarked that the difficulties of the subject are extremely

great. In his last paper this chemist abandons his views as to the existence of silver hemioxide, so that at present the formation of Ag_2O by Wöhler's method, or by any other known method, is admitted by no one. That such an oxide may exist appears by no means improbable. The existence of Ag_2Cl and K_2Cl seems almost to involve that of Ag_2O and K_2O . This latter product Davy believed that he had obtained. The black substance which Von der Pfordten formerly regarded as Ag_2O he now takes to be silver hydrate, $\text{Ag}_2\text{H}_2\text{O}$.

The reduction products described by Von der Pfordten are strongly distinguished from those which I shall presently describe by two decisive reactions:—

1. None of his products could be amalgamated with mercury; all of mine readily amalgamate.

2. None of my products give off the slightest trace of gas when treated with dilute sulphuric acid; all of his do so.

Moreover, the difference of appearance is extremely great.

Early in the year 1886 I took up the study of the reduction products of silver in connexion with that of the protosalts. I commenced with Wöhler's process, giving it up after a few trials as affording no satisfactory results, and sought for a more reliable means. This I found (in March, 1886) in a reaction which I still use, namely, the reduction of silver citrate by ferrous citrate. At first, however, the results obtained were most enigmatical, the products very unstable and impossible to purify. Much time was lost, and the matter was given up more than once as impracticable. Eventually, by great modifications in the proportions, stable products, and capable of a fair amount of purification, were got. Even the earlier and less pure forms were beautiful; the purer are hardly surpassed by any known chemical products.

The forms of allotropic silver which I have obtained may be classified as follows:—

A. Soluble, deep red in solution, mat-lilac, blue or green while moist; brilliant bluish-green metallic when dry.

B. Insoluble, derived from A, dark reddish-brown while moist; when dry, somewhat resembling A.

C. Gold-silver; dark bronze whilst wet; when dry exactly resembling metallic gold in burnished lumps.

Of this form there is a variety which is copper-coloured, insoluble in water, and appears to have no corresponding soluble form.

PROPERTIES POSSESSED BY ALL THE VARIETIES IN COMMON, AND DISTINGUISHING THEM ALL FROM NORMAL SILVER.

All these forms have several remarkable properties in common.

1. *That of drying with their particles in optical contact, and consequently forming a continuous film.*—If either is taken in a pasty condition and is spread evenly over paper with a fine brush it takes on spontaneously in drying a lustre as high as that of metallic leaf. C when so treated would be taken for gold leaf, but this property is much better seen by brushing the pasty substance over glass. When dry, an absolutely perfect mirror is obtained. The particles next the glass, seen through the glass, are as perfectly continuous as those of mercury amalgam, and the mirror is as good. A and B form bluish-green mirrors; C, gold or copper-coloured mirrors.

2. *The halogen reactions.*—When any of these allotropic forms of silver are brushed over paper, and the resulting metallic films are exposed to the action of any haloid in solution, very beautiful colourations are obtained. The experiment succeeds best with substances that easily give up the halogen, such as sodium hypochlorite, ferric chloride, iodine dissolved in potassium iodide, &c. But indications are also obtained with alkaline salts, such as ammonium chloride, &c., though more slowly and less brilliantly. With sodium hypochlorite the colours are often magnificent, intense shades with metallic reflections reminding one of the colours of a peacock's tail. Blue is the predominating tint. These are interference colours, caused by thin films; but whether of a normal silver haloid or a hemi-salt cannot be said. When silver leaf (normal silver) is fastened to paper and a trial made the contrast is very striking. This matter will be more particularly examined in the second part of this paper, and is mentioned here as one of the reactions distinguishing allotropic from ordinary silver.

3. *The action of Acids.*—The stronger acids, even when much diluted, instantly convert the allotropic forms of silver into normal gray silver; even acetic acid, not too much diluted, does this. It is important to remark that this change takes place absolutely without the separation of gas. I have more than once watched the whole operation with a lens, and have never seen the minutest bubble escape.

4. *Physical condition.*—All these allotropic forms of silver are easily reduced to an impalpable powder. One is surprised to see what is apparently solid burnished metal break easily to pieces, and by moderate trituration to yield a fine powder.

A.—SOLUBLE ALLOTROPIC SILVER.

A solution of ferrous citrate added to one of a silver salt produces instantly a deep red liquid (ferrous tartrate gives the same reaction, but is less advantageous). These red solutions may either exhibit tolerable permanency, or may decolourise, letting fall a black precipitate. It is not necessary to prepare the ferrous salt in an isolated form, a mixture of ferrous sulphate and sodic citrate answers perfectly.

When, however, concentrated solutions are used with a large excess of

ferrous sulphate and a still larger one of alkaline citrate, the liquid turns almost completely black. It should be stirred very thoroughly for several minutes, to make sure that the whole of the precipitated silver citrate is acted upon by the iron. After standing for ten or fifteen minutes the liquid may be decanted, and will leave a large quantity of a heavy precipitate of a fine lilac-blue colour. It is best to adhere closely to certain proportions. Of a ten per cent. solution of silver nitrate, 200 c.c. may be placed in a precipitating jar. In another vessel are mixed 200 c.c. of a thirty per cent. solution of pure ferrous sulphate, and 280 c.c. of a forty per cent. solution of sodic citrate. (The same quantity of ferrous sulphate or of sodic citrate in a larger quantity of water will occasion much loss of the silver product). I think some advantage is gained by neutralising the ferrous solution, which has a strong acid reaction, with solution of sodium hydroxide, as much may be added as will not cause a permanent precipitate. To the quantities already given add about 50 c.c. of a ten per cent. soda solution. The reaction takes place equally well without the soda, but I think the product is a little more stable with it. The mixed solution is to be added at once to the silver solution.

The beautiful lilac shade of the precipitate is rather ephemeral. It remains for some time if the precipitate is left under the mother water; but when thrown upon a filter it is scarcely uncovered before the lilac shade disappears, and the precipitate takes a deep blue colour without losing its solubility. It may be washed either on a filter or by decantation with any saline solution in which it is insoluble, and which does not affect it too much. On the whole, ammoniac nitrate does best, but sodic-nitrate, citrate, or sulphate may be used, or the corresponding ammonia salts. Although in pure water the precipitate instantly dissolves with an intense blood-red colour, the presence of five or ten per cent. of any of these salts renders it perfectly insoluble. I have usually proceeded by adding to the precipitate (after decanting the mother water as completely as may be, and removing as much more with a pipette) a moderate amount of water; for the above quantities about 150 c.c. Much less would dissolve the precipitate but for the salts present; this much will dissolve the greater part but not the whole, which is not necessary. A little of a saturated solution of ammoniac nitrate is added, just enough to effect complete precipitation. M. CAREY LEA.

(To be continued.)

FIGURES IN LANDSCAPE AND GENRE.*

LUCKILY, besides mechanical objects of human use, which may serve in landscapes as substitutes for the presence of man, there are two whole classes of models which are practically free, at any rate, from self-consciousness, if they compensate for it by other failings—I mean children and animals.

I know that a small child is often justly a natural bugbear to photographers: "It is far sharper than a serpent's fangs to have a toothless child;" and in proportion as the infant learns to obey directions it loses naturalness. But there is an intermediate stage, and we must sometimes risk a plate or two on the chance of a good thing. Children soon forget constraint, and are generally ready for play: their feelings and expressions are more on the surface and more self-evident; even if they are not beautiful, they have a grace and freshness wanting to plain middle age; there are larger possibilities and greater adaptability about them; and, lastly, they are the only subjects for nude studies possible to photography.

A great deal of abuse has been heaped on the Academy Baby which blossoms in such large numbers every May at Burlington House, and the execrations and scorn were not altogether undeserved. In every corner there seemed to be a pinky infant or two with waxen flesh and vacant sentimental smile, and it was not only the corners or the sky lines which were so tenanted. But these darlings of the British matron were so bad because they were so artificial, and though the camera might not make them so sweetly pretty, yet it would turn out a version much closer to nature and much less repulsive to art.

To turn to history. No subject was more monotonously common than the Virgin and Child, to which was often added the infant St. John. This particular version of the religious picture would never have been so multiplied from ecclesiastical reasons alone, had it not answered to the requirements of art and the deeper needs and affections of human nature. But in spite of occasional traces of realism, of independent study from nature, childhood was hardly appreciated before the rise of the English school of painting, and there has been a further development in the present century. However this may be, much of the charm of children lies in fleeting expressions and sudden turns, and to capture these no means has yet been devised so prompt as the camera. If any one wants suggestions for subjects, they lie in abundance in Mr. Lonis Stephenson's *Child's Garden of Verses*; indeed, the whole book might be illustrated by photographs, if only they could be perfect enough.

From children to animals is an easy transition, for they have many merits and many failings in common. As the value of animals arises from the fact that they do not subject themselves to our will, and so retain their own natural expression and attitude, they are of necessity hard

to manage and to arrange. But they will stand a good deal of handling without acquiring the painful look of some worried adult human models; they are generally to be found in some appropriate localities in the fields (you remember Constable), and we need have no scruples about taking up their time or paying them for their services. Their fashions do not change in fur or feather; they have the beauty of nature with few of the drawbacks of civilisation, and they are near enough to humanity for their expressions to be intelligible, and yet different enough not to be anything else than inferior. Not only are they good in themselves, but they react usefully on any lord of creation who is taken along with them; they are so unconcerned and there is so much in their looks and actions to interest the man, that he may even forget himself for a moment and look as natural as his dog or horse. At times they are unmanageable, and both wear and cause expressions neither happy nor free from anxiety. Infinite patience and experience, many small devices and much knowledge of animal nature, may be necessary for success, but these are excellent things in themselves, and not too much to demand from the perfect photographer.

Of course, we are almost entirely confined to animals domesticated or semi-domesticated, and are at a great disadvantage compared with the painters, who can insert the shyest of birds or most nocturnal of beasts in a light and locality suitable to it, while we have been forced to conclude that unless the creature could actually have been seen and photographed in life, as it is shown in the print, it cannot be inserted at all.

For animals, as I have said, very short exposures are often useful, and sometimes absolutely necessary. I then dwell on the fact that certain instantaneous attitudes are wrong because they can never be seen by human eyesight, and so are not real to us; and I need not go over that ground again. But besides being offences against reality, they are also wrong in art, because they have not that permanency and stability which are required in a permanent representation. Dr. Stillman's theory of the horse in motion, as laid down in Mr. Leland Stanford's book, is "uniform support to the centre of gravity and continuous propulsion of each extremity in turn;" and many of the attitudes are such as can only be maintained for a brief instant. Now, though the best art often represents life and action, yet it selects the typical, the representative crises, and never the intermediate transitions. For instance, there was a picture posted all over London a few years ago, I think an advertisement of a "penny dreadful:" a girl throwing herself off a bridge was suspended between the parapet and the river, and never fell any further. If any copies of the abortion survive, no doubt she is there still, not an inch nearer to the water yet. In like manner some of these instantaneous attitudes are bad art, not only because they are unreal, but also because they are forced into an unnatural and incongruous existence—they are only possible as rapid transitions from one pose to another, yet they are isolated and perpetuated on paper which can never change or explain them.

GRAHAM BALFOUR, M.A.

[JACK AND I IN NORWAY.

BERGEN TO MOLDE.—III.

On leaving Bergen we took steamer to Molde, the furthest point we intended to go, taking all the surrounding places of interest, gradually wending our way back to Bergen again. We got on board the steamer close on midnight. It was quite light then; the porters hurrying with the passengers' luggage, and the knots of parting friends on the quay, could be seen as distinctly as if it had been midday. When it never gets dark like this we forget the time and wonder why sleepiness should overtake us. The boat was crowded to excess, and all the berths being engaged we had to put up with sofas in the cabin: passengers were lying about everywhere. We took about twenty-two hours to go this trip. The weather was beautiful, and we photographed from the deck of the steamer all the way, from early morning right on. Most of the pictures were taken at the various ports at which we called. At some of these places we stayed quite a long time; at one small port we lay for about a couple of hours. Here we made four exposures that turned out first rate negatives. We called at many places *en route*, but there is scarcely such a thing as landing at quays on the trip. The passengers and luggage are transferred from the steamer to the town in small boats, and the visit of the steamer seems to be the great event of the day, as looking over the side one can see the little boats dancing on the wavelets in dozens between the harbour and our ship—some of these on business intent, such as the post boat, others with passengers, and two or three more with the goods traffic of the place, but most of them come as pleasure seekers only, intent on seeing what the passengers are like to-day. One of the principal features of the journey was watching the loading and unloading of the luggage boats, as part of the cargo in most cases were horses and cows, and the swinging up of these poor brutes from the small boats to the deck of the steamer was always interesting. The variety of temperament displayed was a source of great amusement to us. We saw all sorts—some with energy and fire enough to bash out the sides of the boat if they had got free play, whilst others were so stolid and quiet that you could have done anything you liked with them. There was always a crowd on the hurricane deck during this performance of transhipment.

* Concluded from page 431.

Quite a crowd of the sporting class were on board on the way to their fishings and shootings. Jack got on very friendly terms with one gentleman, who was travelling with his family to his summer residence beyond Molde. He turned out to be an enthusiastic photographer, so Jack and he were in the thick of the art-science in no time. Every camera, lens, and shutter in the market were overhauled and descanted upon. The shutter that this gentleman used I never heard of before (but that's not wonderful), Forman's patent I think he called it; at any rate, it could do anything and everything. You could time your exposure from instantaneous right down to as slow as you liked. He did not care for the "Place" shutters we were working, but in spite of his adverse opinion I told him that for general utility I had found them about the best shutters going. They lacked one important thing, I allowed—one never could get the most rapid exposures with them. For ordinary subjects and conditions (always excepting very rapid exposures) I find it the best shutter to carry, even suppose you carried another one for extremely rapid exposures. Our English friend had everything of the newest construction at that place of his (he was not carrying them with him then), and the names of the makers that he gave us was sufficient guarantee that the apparatus must be first class. He spent the summer in Norway every year, and on this occasion he had brought along all his belongings—wife, family, friends, and domestics, in all about twenty, I should say, so that they spread themselves over the place pretty considerably; but they were a jolly lot for all that.

On board we had Birmingham men and Manchester men on the way to their yearly fishing. "Birmingham" especially was full of it, and talked fishing and nothing but fishing to everybody about. He had gone there for years; not a proprietor or fisher for miles round his little place but what he knew, not a season's take of any of them but he could tell you to a pound. It seems that they compare notes at the end of the season, showing who was first, second, &c., according to the success of their takings.

One advantage that you gain in travelling by water here is the way they arrange the fares. You are only charged at the rate of mileage direct to the place you book for, no charge being made for the many fjords that you are taken through on your journey, this on long routes being many miles, so that in lots of cases a day's sailing can be had at a ridiculously small charge; also deductions are made for families or parties, and when husband and wife travel together they are taken at a cheaper rate. The captain told me a good story about a man and his wife travelling by his boat. The husband came to get the tickets, and the wife, fearing that he might forget about the allowance, called out to her husband, "Don't forget your wife," when the captain with a smile replied to her in English, "We never forget our wives in Norway."

Out from Aalesund on our way lay the Island of Lepsöe, which has become a spot of considerable interest since Mrs. Mount from Shetland, the lonely woman of the ocean, was driven in upon its friendly shores. All will remember the interest the incident created at the time. On a voyage from one port to another in the Shetland Isles the smack *Columbine* had her skipper washed overboard; there were only two other sailors on board, who immediately lowered a boat and set out in search of their captain. Their search proved unsuccessful. On turning to come back to the smack, what was their horror to see it under weigh and speeding along at such a rate that it was beyond all hope to get near it, and only one poor woman on board, also an ailing woman, who had been on her way to see the doctor. This was Mrs. Mount, and she was given up for lost. After a week's buffeting with winds and waves, and having no food on board save a few biscuits, worn out and nearly dead, the boat in which she lies drives in and lies stranded on the shore of the Island of Lepsöe, where the kindly natives attend to the helpless wanderer, who when restored returns to her native land and becomes the heroine of the day.

When reaching Edinburgh on her journey back she was photographed of course, and thousands of her pictures were sold. Some showman wanted to engage her at a big price, but she preferred going home; she thought she had travelled far enough.

We got into Molde about 10 o'clock p.m., and were put out in a small boat from the middle of the bay. Stayed at the Alexandra Hotel, where we had very comfortable quarters. Being amongst the first, if not the very first, visitors of the season, the landlord's face beamed all over smiles when he saw Jack, for he knew him at once. "I hope you bring good luck for the summer," he said, as he grasped his hand. Jack without a moment's hesitation promised him a good season.

In the morning we were up early and out with the camera. The sun was shining brightly and it was delightfully warm, the heat tempered by a cool breeze from the snow-covered mountains that surround the town, the snow looking quite pink in the red rays of the morning sun. Molde is but one street that zigzags along the shore, terminating at the end nearest our hotel in a picturesque avenue of small trees. The mountain at the back of the town is the spot from which the visitor obtains the most extended view of all the surrounding fjords. The most of the houses look old and antiquated, except the hotels; they are all made of wood. The shops are meagre, small-windowed places, with a poor array of stock; in one or two of the old silver shops they showed about six or eight ounces of manufactured goods in the windows, and the interior looked as if there was not much more there. The places of business comprised the furrier, the general dealer, and the old silver shops, and all of these are of the most primitive order.

There is a lepers' hospital at Molde. There are three altogether in the country—one here, and one each at Bergen and Trondhjeen. We understood that we might be allowed to visit the one here, but it was too sad a sight and we did not go. Why Norway should be so subject to such a terrible disease is not well understood; the living so much on fish, and that being partaken of to a large extent in a raw state, is assigned as a likely cause. They say that it is being gradually stamped out, which must be a source of great comfort to the natives of the country.

We got some good pictures of the place, considering our limited stay—one very good one of the Alexandra. We then started on our further journey in a little steamer called the *Molde*, not nearly so big as one of our river tugs, and after a twenty miles' sail we landed at Veblungnes.

MARK OUTR.

Foreign Notes and News.

The French Minister of Commerce has appointed a Committee for the purpose of organizing an International Photographic Congress to be held during the Paris Exhibition. The Committee, headed by the well-known astronomer, Prof. Janssen, have already commenced work. The Congress will meet from August 6 to August 17, and discuss the following subjects:—(1) Introduction of a uniform photometric unit; (2) Uniform measurements of focal lengths of objectives; (3) A uniform scale for the determination of the photometric effect of objective diaphragms; (4) Uniform periods of exposure in instantaneous work; (5) The adoption of a uniform and easily applicable method for fitting different objectives on to cameras; (6) A universal form of plate; (7) A uniform terminology for photographic operations; (8) Universal agreement of photographic formulae; (9) Uniform adjustment of Customs procedure with regard to substances sensitive to light; and (10) Protection of artistic copyright in photographic works. A Conference, in which the work of the Congress will be publicly discussed, is to take place on August 20.

PROF. DR. VOGL has been raising the question of the sensitiveness to colour of erythrochrome silver plates, which he maintains act quite well without the employment of a yellow disc, and instances photographs taken by the thousand for the last five years by Braun (Dornach), Hanftaengl, Bruckmann, and others, on eosine-collodion plates for which no light filter was employed. We must, however, remember that collodion plates possess relatively to gelatine plates a much greater sensitiveness for yellow than blue; and consequently that it does not follow that the yellow disc may be omitted with equally good effect in the case of these latter.

PROF. DR. J. M. EDEN has been examining the crystallised hydroquinone manufactured by Dr. H. Byk in Berlin, which contains $\frac{1}{2}$ to $\frac{1}{4}$ per cent. sulphurous acids, and has also compared it with the ordinary white variety. The former, both in simple solution and in the presence of sodium sulphite and alcohol, proved itself to be markedly more permanent than the latter, and to preserve its pre-eminence, though less noticeably in this respect, even when employed in developing solutions containing alkalis; the developing capacity appeared the same in both.

Our Editorial Table.

W. B. BOLTON'S FILM CARRIERS.

SINCE Mr. John Carbutt, of Philadelphia, hit on the happy thought of substituting translucent films of celluloid for glass plates as supports for sensitive gelatine films, the means for keeping these films rigid while in the dark slide have exercised the inventive faculties of many. The film carriers before us form the outcome of the consideration and the inventive abilities of Mr. W. B. Bolton, and they are withal so good and so simply made as to put in the shade anything we have previously seen. They are formed of an exceedingly thin plate of metal, with two edges turned over so as to retain the flexible films *in situ* and closely pressed against the supporting back. On the reverse side the opposite edges are also bent over, and thus render it capable of receiving another film. Each film carrier is thus composed of a thin metallic plate, to which two films are attached, the one by the sides and the other by the ends.

These film carriers are rigid and remain flat. They will prove of great convenience where space is a matter of consideration, as quite a large number of them can be carried in the inside of one of our ordinary double dark slides. A patent has been applied for for this

invention, which, from its intrinsic merits, will certainly secure for itself a large demand.

Since writing the above we have received from Mr. J. M. Turnbull, 6, Rose-street, Edinburgh, one of the film carriers which he manufactures. It consists of a plate of thin metal with the edges turned over in three directions, under which the film is slipped and kept in position by these overlapping edges. It will, no doubt, answer well its intended purpose.

JAMES MARTIN'S NEW PRICE LIST.

THE trade price list of Mr. James Martin, of 4 Park Villas, New Southgate, N., is neat and methodically compiled. Mr. Martin's speciality is printing and enlarging, and one can at a glance ascertain the prices, plain or vignette, of every size of print from the smallest to the largest, in either albumenised silver, platinotype, aristotype, bromide, or ferroprussiate. Equally well classified are the enlarging, mounting, copying, and finishing branches of Mr. Martin's establishment. Mr. Martin's skill in these several departments is too well known to need allusion.

JONATHAN FALLOWFIELD'S MONTHLY PHOTOGRAPHIC REMEMBRANCE AND TRAVELLER.

THE monthly differs from the magnificent annual of this well-known firm in that it provides for the special requirements of the month in contradistinction to those of the year. This one is a double number for the midsummer months, and contains a classified and copiously illustrated collection of those photographic appliances specially suitable for the season—and not for one season only, but for all times. All kinds of plates, all makes of paper, mounts, chemicals, and requisites in general are here to be found.

PATENTS COMPLETED.

IMPROVEMENTS IN PHOTOGRAPHIC CAMERAS.

No. 1278. HENRY NORTON BUTLER GOOD, Shrewton Lodge, Devizes.—*January 23, 1889.*

This invention relates more especially to photographic cameras in which pictures are taken upon a film or strip of sensitised material, the position of which can be adjusted as and when required, so that after each picture has been taken a fresh part of the sensitised strip can be brought into the proper position to take a fresh picture, and so on until the whole of the sensitised strip or film has been utilised.

In such cameras as heretofore used the strip or film of sensitised material is wound upon a roller which is inserted into a separate slide and attached to the camera, and is wound off the said roller as required, and rewound (after the pictures have been obtained upon the sensitised surface) upon another roller carried by the removeable slide; and my present invention has for its objects novel methods of construction by which the camera and lens, and the devices for carrying and moving the film as required are united in one, instead of being separate, space is greatly economised, and the entire apparatus is very cheap, light and portable, and effective.

It is more especially applicable to small cameras in which a series of instantaneous pictures can be taken at any desired moment.

My improved apparatus consists of a box or case of suitable size, preferably rectangular, and of wood or other material. In front of this box there is an opening provided with an instantaneous or other shutter of any of the ordinary well-known kinds by which the opening can be opened or closed for the purpose of obtaining a picture.

Behind the shutter I arrange in the box a transverse partition carrying a lens of the required size and focus, and at the back of the partition I arrange two lateral vertical partitions, the front edges of which join the front partition at each side of the lens, whilst their back edges separate until they nearly reach the sides of the box at a short distance from the back. In the angular spaces thus formed behind the front partition I arrange the holding roller or spool and the receiving roller respectively, the former having the sensitised strip or film wound upon it, the end of the strip being led from it backwards, then across the space between the back ends of the lateral partitions, and again for-

ward to the receiving roller, to which it is fastened, so that when the latter is turned round the strip is wound upon it, and at the same time unwound from the full roller or spool.

At or near the back edges of the lateral partitions I arrange vertical rollers or guides, preferably of glass, or of wood or other material covered with glass, round which the film passes and is guided with very little friction or risk of abrasion. Upon the interior surface of the top and bottom of the box or camera, just in front of the sensitised strip or film, as it passes across the back, I arrange two transverse strips of wood or other material, behind the edges of which the edges of the strip pass, and against which they are pressed with sufficient force by a flat plate of vulcanite or other suitable material, which is pressed against the back of the strip by a screw passing through the back of the box, or by other equivalent device.

At the back of the vulcanite plate a transverse metal spring is arranged, one end of which is fixed to one edge of the plate, whilst its other end is pointed, and is sufficiently long to be bent forward and project slightly in front of the plate.

When the film or strip has been adjusted in the proper position to receive a picture from the lens, the vulcanite plate is pressed forward by the screw so as to hold the edges of the film firmly in position against the top and bottom strips, the point of the screw first pressing forward the spring, the pointed end of which marks the paper from the back sufficiently to indicate the position of the picture upon it when it is ultimately removed from the rollers for the purpose of being cut up and developed in the usual way. Small springs are arranged to press back the vulcanite plate from contact with the back of the film when the pressure of the screw is withdrawn.

In one of the angular spaces first described between the front partition and the lateral vertical partitions, I arrange a vertical roller, against which the film or strip presses, and which is made to revolve by such pressure when the rollers are made to revolve and draw the strip forward.

The axle of this roller passes through the top or bottom of the box or camera and is provided with a toothed pinion actuating an indicating device, by which it can be seen when the film has moved exactly sufficiently forward to present the proper surface for a new picture, and also if desired to show the number of exposures which have been made and pictures taken.

The rollers which carry the sensitised strip or film are made readily removable, so that they can be taken out and replaced as desired, their centres turning upon screws in the top and bottom of the box or camera, which can be screwed up or unscrewed as desired. The receiving roller is fitted at one end to a socket, either end of which can be turned round by a suitable key or handle for the purpose of turning the roller and so causing the strip or film to pass behind the lens as already described. I prefer to make the key removable and with a solid end, square or of other suitable form, which fits into a corresponding hole in the end of the socket which turns the receiving roller; and the same key may also fit into similar recesses, which carry the other centres for the rollers, and in this way no projecting part is necessary outside the box or camera.

Either or both the rollers may be provided with ratchet wheels and pawls, or their equivalents, by which the rollers are prevented from turning in the wrong direction, and spring or other brakes may be arranged so as to press upon the strip upon the rollers, or upon brake wheels upon the roller sockets, and so keep the rollers from too easily unwinding and thus allowing the strip to be imperfectly stretched.

A flat piece of transparent glass may be arranged in front of the strip or film, the latter being pressed against it by the vulcanite plate at the back.

By the improved methods of construction and arrangement which constitutes my invention great economy of space is effected, the rollers for holding the strip or film being placed so as to occupy the smallest possible space. The flexible strip or film is wound upon the roller so that as it passes in front of the vulcanite plate it has no tendency to curve or buckle outward, but rather to remain flat in contact with the plate and so to ensure perfect pictures. Great advantage is thus obtained, since when the strip or film is wound and used in the way described its surface is flatter, even if the vulcanite plate be altogether removed, than when wound in the manner ordinarily hitherto used.

I preferably arrange the receiving roller so that when it is filled with the exposed strip or film it can be very easily detached from its sockets, and an empty one substituted, so that it is not necessary to unwind the strip from the receiving roller. Springs or hinged clips of equivalent devices are attached to the rollers for the purpose of fastening the ends of the strip or film, and the receiving and supplying rollers are made alike and interchangeable so that they can be used for either purpose.

Meetings of Societies.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JUNE 27.—Mr. W. E. Debenham in the chair.

Being the annual meeting, the report was read by the Secretary, and an opinion was expressed that it would be desirable to arrange outdoor meetings of the members during the summer months, and to reorganise a system of

lecturettes for the winter session, such as had been introduced by Mr. Haddon in some previous years.

The consideration of the balance sheet was adjourned to the next meeting, and the election of officers was proceeded with, resulting in the following appointments:—*Trustees*: Messrs. J. Traill Taylor and J. B. B. Wellington.—*Committee*: Messrs. Atkins, Atkinson, Briginshaw, Clifton, Debenham, Everett, Freshwater, and Moran.—*Cumtutor*: Mr. A. Haddon.—*Secretary and Treasurer*: Mr. F. A. Bridge.

The subject appointed for the evening's discussion was *The Practical Testing of Lenses*, and the Chairman having invited Mr. J. TRAILL TAYLOR to open the discussion, that gentleman remarked that the lenses to be tested should have the diaphragms removed, and that the photographer's method of practically testing lenses was by using them in the camera, but that opticians did not usually resort to that method. They generally employed a small artificial star consisting of the reflection from the mercury in a thermometer bulb placed at a short distance from a lamp. This star takes a different appearance when within and beyond the focus, and from the greenish border which it assumed when in one direction, and the claret-coloured border which it wore in the other direction, the optician was perfectly well able to test the lens for achromatism. A lens to work true to focus in the camera should be under-corrected as far as regards its visual effect. Flatness of field was another quality for which to test lenses. Mount the lens in a camera and look at a distant view, when if the centre was in focus the image at the margin was almost certain to be out of focus. Next see whether it is possible to get focus at any part of the field, if so the lens is free from spherical aberration, but with freedom from spherical aberration and astigmatism the field was round. The correction given to lenses when intended for standing figures was to obtain a considerable amount of flatness of field at the expense of some astigmatism. It was desirable to have lenses of the rapid doublet or Steinheil type set in a mount in which there was a certain amount of adjustment possible, so as to get greater flatness of field by separating the lenses, and greater freedom from astigmatism by approaching them together. If asked whether it was possible to have a lens which should include a wide angle of view and at the same time have a large aperture, he should until quite recently have replied in the negative, but the new kinds of optical glass recently manufactured had extended the possibilities of combining various advantages, and he had quite recently seen a lens, which would be described in the photographic journals, that really did possess both a wide angle of view and a large aperture. With single lenses it was impossible without a diaphragm to get sharp definition with the flatter side outwards, but on the other hand, if the flatter side was next the plate, the definition was confined to the centre of the field, a very small area. Telescopic lenses gave the most perfect definition conceivable when used as in telescopes with the more convex side outwards, but the field was sharp only just in the centre. He had single lenses that would give sharp definition and be suitable for portraiture with an aperture of $f/8$. When further stopped down, a field of 50° or 60° was covered. It was convenient to remember that if the length of the plate was equal to the focus of the lens, the angle included by the length of the plate was 53° . For testing for astigmatism it was convenient to focus a sharply defined cross, such as that made by the sash bars of a window. When it is attempted with a lens possessing astigmatism to focus such a cross near the margin of the plate that it would be found the vertical and horizontal lines forming the cross could not be got to focus at the same time, the lens would have to be turned in for one line and out for the other. Miethé, a German optician, claims to have invented a lens in which flatness of field and freedom from astigmatism are combined. From what Vogel says of the lens it must resemble one recently patented by Dr. Schroeder, the conditions of which are that the doublet is formed of two deep meniscus lenses, the surfaces of which are nearly concentric. A lens of this kind made of any single glass would be negative, and would not form an image, but by combining different glasses a positive lens capable of yielding an image could be formed, and with the new glass chromatic aberration could at the same time be corrected. To see if the glass of any lens was free from spots and defects, hold it between the eye and a source of light, such as a gas flame, at such a distance that it appears to be full of light. Then by turning it about any defects become evident. For seeing that the glass of a lens is as free from colour as possible, take out the lenses and lay them on white paper, when the colour is readily seen.

The CHAIRMAN considered that it required the practised eye of an optician to test lenses for chromatic aberration by observation of the colour of the fringe of light when within and beyond the focus. A convenient way for the photographer was to use Claudet's focimeter, but with type of varying degrees of fineness on each arm of the instrument. A method requiring no special apparatus was to focus a piece of newspaper placed much upon the slant. If at the centre of the field certain words came out sharply on the focussing screen, and words at a greater or less distance came sharp in the negative, the lens did not work true to focus, and the amount which it had to be racked in or out to get the same words sharp on the focussing screen that were sharp on the negative was the measure of the chromatic aberration. It was, of course, supposed that the camera was in itself true in its adjustment of focussing screen and plate holder. Flatness of field he held to be very important, and the manner in which he tested for it was to arrange the camera so that it could be swung round without much displacement of the lens, and to focus some distant object, first in the centre of the field, and then at measured distances, say an inch apart upon the focussing screen. The amount which the lens had to be turned in for each fresh focussing was measured, and by plotting these distances out on paper the curvature of field for the particular lens was shown.

It was announced that Mr. Scotton would demonstrate the blue iron printing process on Thursday, July 11.

UNIVERSITY COLLEGE PHOTOGRAPHIC SOCIETY.

JUNE 25.—Dr. R. T. Plimpton in the chair.

Mr. A. GRYK exhibited some negatives which were covered with dark spots, and asked the opinion of members as to their cause. No satisfactory explanation could be given—dust, irregular development, and the action of the paper used in packing upon the film were suggested as possible causes.

Dr. PLIMPTON then resigned the chair to Dr. H. Foster Morley and proceeded to give a demonstration of the hot bath platinumotype process, after which Mr. LEON gave a similar demonstration of the Platinumotype Company's cold bath process, for which he claimed a greater power of control over the quality of the print produced than by the older method.

A discussion took place in which most of the members joined, the most important question raised being the relative cost of the two processes. Doubts were raised as to the possibility of developing the quantity of paper stated on the Company's labels with the given quantity of platinum salt by the cold bath process, except perhaps in the case of large quantities.

The Society made an excursion on Saturday, June 29, to Elstree.

The next meeting, Tuesday, July 9, will be the annual general meeting of the Society, at which the present officers and Committee will be proposed for re-election.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

JUNE 27.—Mr. A. W. Beer in the chair. There was a very good attendance of members.

The PRESIDENT referred to the loss the Association had sustained in losing the services of Mr. W. A. Watts, their Honorary Secretary. A better or more capable gentleman it would be difficult to find, and it was now his pleasurable duty to submit the Council's nomination, viz., "That Mr. W. A. Watts be elected as an honorary member," which was carried unanimously.

The Council had elected Mr. W. Hughes, their Hon. Secretary, as successor to Mr. Watts.

Mr. G. R. Johnson was elected a member of the Association.

The House Committee's statement of expenditure incurred in the alteration, fitting-up, and furnishing their rooms amounted to 149*l.* 5*s.* 4*d.*

The PRESIDENT hoped it would be satisfactory to the members, and, judging from their present comfortable quarters, he thought the money had been advisedly spent.

The leader of the excursion on June 1 to Burton and Ness, and of the excursion on June 15 to Speke Hall, Old Hutt, and Hale, gave particulars of their respective trips. Fifteen joined in the former and were fortunate in the weather, one hundred and two exposures being made and good results secured. Respecting the latter, the party numbered forty-nine; two large wagonettes were requisitioned for the occasion, and a most enjoyable day was pleasantly spent, two hundred and twenty-nine exposures being made.

Attention was drawn by the HON. SECRETARY to the excursion on Saturday, the 29th instant, to the Bollin Valley, near Bowden, Manchester, a prize of a bronze medal being offered for the best picture, irrespective of size. The party would be met at the Central Station, Manchester, by Mr. James Davenport, Vice-President of the Manchester Amateur Photographic Society, who had very kindly offered to act as conductor.

Mr. PAUL LANGE gave his demonstration on *Enlarging*, using the Society's enlarging camera recently purchased for the use of members, and proceeded to make an enlargement from a half-plate positive to a negative 15×12 . He found the most satisfactory results were obtained by first securing a good small-sized positive by contact, from which the desired negative could be obtained and any number of prints could be supplied. Enlarging direct on bromide paper was not certain, and only one copy could be made, whereas a good negative once secured was always ready and the results uniform. For enlarging purposes he preferred a tinted positive, such as the colour produced from soda development, the effect of the colour tending to soften the shadows. The formula he used was:—

	No. 1.	
Pyro	3 grains.	
Water	2 ounces.	
	No. 2.	
Washing soda	2 ounces.	
Ammonio-bromide	40 grains.	
Water	16 ounces.	

He explained, for the benefit of those who had not hitherto tried to enlarge, the various parts of the camera and uses of all the adaptations with which it was fitted, and congratulated the members on such a valuable acquisition to the rooms, and hoped his few remarks would induce many to use it. The lens was a nine-inch doublet, $f/16$, with thirty seconds' exposure at six p.m., bright sunlight, resulting in a very satisfactory negative.

A vote of thanks was then accorded Mr. Lange for his interesting demonstration.

Prints were exhibited on the screen for the inspection of members, taken at the recent excursions by Messrs. Beer, Tomkinson, Timmins, Tunstall, Mackrell, Thomas, Wilkinson, and others, some of which were greatly admired for artistic excellence.

BATH PHOTOGRAPHIC SOCIETY.

JUNE 26.—Mr. Austin J. Klog in the chair.

Messrs. J. Mendum, W. Hinds, and W. H. Davies were elected members.]

A communication from the President was read inviting the Society to a garden party upon his return from Switzerland.

The CHAIRMAN pointed out that fuller details would be announced later. The Committee did not think it necessary to interfere with the regular excursions; that fixed for July was Chepstow and Tintern, which would occupy a whole day, and the month of July had been chosen on account of the light. The garden party would probably take place towards the end of the month, and he hoped both meetings would be well attended.

The SECRETARY drew attention to a new monthly paper entitled the *Optical Magic Lantern Journal and Photographic Enlarger*, specimen copies of which had been presented to the Society.

The receipt of Vever's *Practical Amateur Photographer* and various circulars having been announced, Mr. FRIESE GREENE read a paper entitled *Colour, its Study and Relation to Photography; also the Taking of Pictures on Opal*

Cards [this will appear in a future number]. During the delivery Mr. Greene showed by means of the spectroscope the colours which are transmitted through such media as ruby glass, and at the close exposed (about ten seconds to gas-light) two of the cards and developed positives thereon. The nature of the sensitive coating was not divulged, nor the method of preparing the cardboard to withstand washing, but other points elucidated were: development of the prints similarly to that of bromide paper by means of ordinary ferrous oxalate restrained with bromide and after slight washing in water fixed in hypo; but instead of prolonged final washing and the use of clearing acid, they are soaked in a three-grain solution of hydroquinone which is claimed to supplant it. Finished examples of the method were shown, and a general conversation ensued concerning the employment of hydroquinone after fixing.

The proceedings terminated with the usual votes of thanks.

THE third excursion of the season took place on the 29th ultimo. A four-in-hand brake left the city about noon for Great Chalfield Old Manor House, Trowbridge, journeying by way of Bathaston and Box. The day was very fine, and the proverbially dusty character of the roads after a long spell of dry weather caused the travellers to arrive at their destination like dusty millers. Cameras were already on the ground, some members having previously arrived in private carriages.

Old Chalfield is the property of Mr. G. P. Fuller, M.P., and is most unique. The church, old manor house, farm buildings—in fact, the entire village—is built within the moat, and must have been a formidable stronghold in bygone times; it dates back at least four hundred years, parts being still older.

The whole village, easily taken with a wide-angled lens from within the moat, was soon attacked by two dozen cameras, but the reminder that luncheon was already spread in a shady nook at Little Chalfield, about a mile off, caused a hasty packing up. Having filled a page in the visitors' book, we adjourned to the new quarters. Here we found our Vice-President (Mr. Austin J. King) had provided a capital spread, which, it is needless to say, was warmly appreciated. While the party were yet reclining in the cool shade afforded by the surrounding elm trees Canon Williams exposed one of the new celluloid films on the assembled guests as a memento of the occasion, but as the worthy Canon was not himself included in the group, another camera was quickly brought into play by Mr. Perren.

A pleasant drive of a few miles brought us to the Old Manor House, South Wrexall, the property of Mr. Walter Long, M.P., and preserved by him exclusively for inspection by visitors. The place is of great historical interest, and abounds in subjects for the camera, the majority of which received attention.

Once more on the road, a good pace was made along the high ground commanding extensive views of Wilts and Somerset and the cloth mills in the valley below. Skirting Bradford Leigh, our road lay through the village of Winsley, which is very quaint and picturesque, but the day was too far advanced to halt. About a mile further on we arrived at Rowas Lodge, the summer residence of Mr. King. Here, upon the spacious lawn in this beautiful and secluded spot, our host again bountifully provided for the party.

Daylight was fast waning when a move was made through the forest glade to the foot of Winsley Hill, where the brake was in readiness for our return to the city, and, after a smart drive, we arrived shortly before ten o'clock, having accomplished a total distance of about thirty miles.

Next outing, July 27, to Chipstow and Tintern.

IPSWICH PHOTOGRAPHIC SOCIETY.

THE monthly excursion took place on Saturday afternoon, June 29, to East Bergholt, which was reached about three o'clock after a pleasant drive of ten miles from Ipswich. Mr. J. Reynolds, a resident member, met the party and acted as guide. The church was first visited. It is a fine building with a nice interior, but the "narrow angles" were quite out of it for both interior and exterior pictures. There is no tower to this church, merely the foundation walls of one, and legend says that the enemy of mankind has so strong an opposition to a steeple being built, that he has always at night demolished any work done the previous day, and the hope of ever completing the tower has therefore been abandoned. The bells, a peal of five, are hung in a quaint wooden structure in the churchyard apart from the church. Having exhausted the village, tracks were made for Flatford, a pleasant walk of a little over a mile. Here are some picturesque cottages, a large mill, and a rustic timber-built bridge. Many of Constable's famous pictures were taken at this pretty spot in the Stour Valley. A return to the Bergholt Red Lion was the next proceeding, and a tea done ample justice to. A pleasant drive home brought a most enjoyable outing to a satisfactory close.

Next excursion, July 28, to Helmingham.

BRISTOL AND WEST OF ENGLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE June excursion meeting of the above Association was held at Bradford-on-Avon on Saturday, the 22nd instant. There was a fair attendance of members, but it was to be regretted that a larger number could not avail themselves of the opportunity.

On arriving at Bradford, the Hon. Secretary acted as guide, and the river scenery below the town was first visited, a reach below the fourteenth-century bridge affording good work.

Members then adjourned to the Swan Hotel for lunch, and afterwards worked for a time among the various old-fashioned byways of the town, where many admirable subjects for the camera exist.

After seeing Kingston House, the Saxon Church, and one or two other places of interest, a waggonette was hired and the party drove to South Wrexall Manor House, an ancient place, now much decayed, full of the greatest interest to artist and antiquarian. The exterior is partly Tudor and partly Elizabethan, and, from its quaintness, very suitable for photographic work. Much of the interior work is also charming, notably the carved chimney-pieces throughout

the building, and the oak panelling of the walls, and plaster Jacobean ceiling of the reception room.

Several hours were profitably spent here before the time came to drive back to Bradford and return home.

The July meeting will take place on Saturday, July 20, Wells being chosen as the spot to be visited. Although there is much work to be done in Wells, it may be useful to state, for the benefit of those who have already taken pictures there, that Glastonbury is within easy reach, and affords abundant material for exposures.

PHOTOGRAPHIC SOCIETY OF PHILADELPHIA.

JUNE 5.—The President (Mr. Frederic Graff) in the chair.

The Committee on Joint Exhibition presented the following report:—

The Third Annual Joint Exhibition of the Society of Amateur Photographers of New York, the Photographic Society of Philadelphia, and the Boston Camera Club, was held in the Galleries of the Pennsylvania Academy of the Fine Arts, Philadelphia, April 8 to 20, 1889, under terms of agreement and rules adopted at a meeting of representatives from the three Societies held in New York, October 22, 1886, revised and amended November 10, 1888. By the revised and amended rules definite regulations were adopted for holding and governing such meetings of the Joint Exhibition Council as may be deemed necessary. All entry of exhibits by classification was abolished, and the awarding of diplomas by classification was limited to the seven diplomas for "special excellence" reserved for the recognition of exceptional merit in certain principal lines of photographic work, one diploma being placed at the disposal of the Judges for each of the seven classes. Your Committee believes that critics generally recognised a marked improvement in the quality of the pictures exhibited by all participants. The increased proportion of bromide and platinum prints was noticeable over former exhibitions, and indicates a change of taste from the warm tones and glossy surface of the albumen print to something more permanent and more pleasing to the eye of the artist. An even greater revolution may be expected within the next year, owing to the introduction of the cold process in platinotype printing and in the new toning of plain silver prints with a platinum salt.

The aristotype and prints made from negatives on orthochromatic dry plates, and prints from celluloid films, were among the newer features of the exhibition. The exhibits of pictures made with detective cameras were interesting in many respects, and no doubt furnish valuable studies for an artist, but in close comparison with larger and direct prints from negatives made with time exposure they suffer in respect to technical qualities and the careful composition so important to a photographic picture. It is to be hoped that the ease and fascination of hand camera work will not induce photographers to neglect the use of the larger plates or films, which, though entailing more cost, care, and labour, repay it all in more satisfactory and pleasing results. We are informed by one of our foreign exhibitors that among landscape photographers of England, who aspire to pre-eminence in their art, larger plates are now in use than ever before.

Exhibitions of lantern slides were held upon Tuesday and Thursday evenings of each week. The improvement in the quality of gelatine lantern slides was marked and encouraging, also the uniform size of slides and neatness in mounting, qualities no doubt engendered by the labours of the American Lantern Slide Interchange.

By special resolution of the Joint Exhibition Council the Board of Judges was to consist preferably of "three artists of acknowledged ability, at least one of whom shall be well versed in practical photography, and two expert practical photographers."

Diplomas were awarded as follows:—

Diplomas for Special Excellence.—1. "For landscape or marine views," Harry Tolley, Nottingham, England (*On the Lonely Shore*). 2. "For portraits," Frederic Gutekunst, Philadelphia (miscellaneous portraits). 3. "For genre subjects and figure compositions," W. W. Winter, Derby, England (*My Mamma*). 4. "For work by ladies," Mrs. S. M. Cleveland, Philadelphia, (entire exhibit). 5. "For enlargements," William H. Rau, Philadelphia. 6. "For lantern slides," Professor Henry A. Rowland, Johns Hopkins University, Baltimore, Maryland. 7. "For applied photography, scientific or technical," Professor Henry A. Rowland, Johns Hopkins University, Baltimore (for photographic maps of the normal solar spectrum, second series, 1888).

Diplomas for Excellence.—"For entire exhibits," Frank M. Sutcliffe, Whitby, England; William Perry, Shields, England; J. P. Gibson, Hexham, England; John Bartlett, Philadelphia; Charles L. Mitchell, M.D., Philadelphia; George B. Wood, Philadelphia; Paul Lange, Liverpool, England; Robert S. Redfield, Philadelphia; Richard Keene, Derby, England; Harry Symonds, Portsmouth, England; S. W. Burnham, Lick Observatory, California; The Rev. F. C. Lambert, M.A., Cambridge, England; H. A. Latimer, Boston, Massachusetts; A. K. P. Trask, Philadelphia; George A. Nelson, Lowell, Massachusetts; R. T. Hazzard, Philadelphia; Clarence B. Moore, Philadelphia; Mr. and Mrs. Anckhorn, Arbroath, Scotland.

While the object of the joint exhibitions is not that they shall serve as a source of revenue to the societies interested, it is gratifying to your Committee to be able to report that the late exhibition was peculiarly a success.

The experiment of conducting the exhibitions of photographers in the three cities—New York, Boston, and Philadelphia—annually, and in rotation, under the same rules and management, now having been given a trial by each of the societies, a proper time has arrived for considering the question of the desirability of a continuation of the plan and agreement. The benefits which have accrued from the co-operation are very apparent; the objects of such exhibitions are identical in each society, and the limitation of one exhibition to each city once in three years keeps fresh and increases the interest taken in them by the public and by contributors.

The three societies now so fully understand and agree upon the general object of the exhibitions, it may be well before entering upon another three years' series for each society to consider whether the plan adopted shall be continued in its present shape of joint exhibitions or whether they would prefer to conduct future exhibitions each under its own rules, confining the

agreement simply to holding the exhibitions annually in rotation in one of the three cities under the control of the local organization. If continued as a joint arrangement it would seem desirable that a medal be adopted for distribution at future exhibitions in place of diplomas. A medal is the time-honoured token for award in recognition of high merit. It is recognised as such in all countries, and conveys an idea of value and dignity which a mere written document or instrument can never equal.

(Signed) JOHN G. BULLOCK, } Committee on Joint
ROBERT S. REDFIELD, } Exhibition.
SAMUEL M. FOX, }

The Treasurer's report showed a balance to be placed to the credit of the Society over and above all expenses on account of the exhibition of about twenty-five thousand dollars.

VEREIN ZUR FORDERUNG DER PHOTOGRAPHIE IN BERLIN.

JUNE 7.—Dr. Vogel in the chair.

The determination of the Association Belge de la Photographie to take part in the coming Jubilee Exhibition of Photography at Berlin was communicated to the meeting, the announcement being received with applause.

The new patent developer, "Eikonogen," which it appeared had previously been mentioned and tested by Dr. Vogel, then became the subject of discussion.

Herr STOLL observed that he had already made some very satisfactory experiments with it, especially in the case of instantaneous work, obtaining very powerful negatives in every case.

Herr VOGEL, jun., remarked that this developer permits a considerable reduction of the time of exposure, and that cases in which, hydroquinone being employed, an exposure of three seconds was necessary, required on employing eikonogen an exposure of only one second; that though plates that developed well and rapidly might be too thin, yet after intensifying they could be made use of. The speaker did not employ a preliminary bath, which Herr Stoll so strongly recommends.

Herr STOLL stated that he had made use of the prescribed alum bath, but found that it made the plates look exactly as if they had gone mouldy, an effect which he attributed to the precipitation of alumina. He, moreover, regarded the alum bath as superfluous.

Herr VOGEL, jun., confirmed the above statements, adding, however, that eikonogen (which, it would appear, is a naphthalin-derivative discovered by Dr. Witt) exercises a hardening influence on gelatine, causing the developing action to be confined to the surface.

Herr STOLL, on the contrary, was of opinion that the plates developed rapidly right through.

Professor Dr. VOGEL announced that the splendid rooms of the Krieg Academie had been obtained for the use of the coming exhibition. The speaker pointed out that the rooms in question offered some 8000 square feet of well-lighted wall surface.

Herr VOGEL, jun., exhibited a new metallic camera by Oertel in Augsburg, entitled the "Invincible." The camera in question is composed entirely of Britannia metal, and folds up like a pocket-book. It may be employed like Anschütz's cameras for photographing objects at high elevations, as it can be given a stable movement by means of a joint attached to the stand.

Herr Anschütz (Lissa) exhibited some instantaneous photographs of the recent manoeuvres. Herr Anschütz operates from a carriage, which enables him to follow the movements of the troops, and prevents his field of view being obstructed by persons in the foreground, which often occurs to photographers on foot, one of whom appearing in the foreground of one of Herr Anschütz's pictures occasioned a good deal of amusement.

The heat caused the meeting to adjourn early, but most of the members resorted to a neighbouring garden, where the fresh air and suitable "materials" contributed to the "development" of sociability, although the liquid employed was not "eikonogen."

Correspondence.

✉ Correspondents should never write on both sides of the paper.

PHOTOGRAPHY IN THE ARGENTINE REPUBLIC.

To the Editor.

SIR,—“Buenos Ayres,” in a back number (March 22) of the JOURNAL, desires information concerning the Argentine Republic, its climate, and the possibilities of obtaining employment as artist, retoucher, &c. The climate is very fine and the winters mild, but the prospects of obtaining employment are not so satisfactory, and I for my part should not advise him to come out here on “spec,” as the River Plate is overrun with photographers, and the supply is far in excess of the demand. We have any amount of applications for employment both here and in Buenos Ayres, and I feel certain that the majority have to take up some other pursuit or leave the country. These are immense countries and are going ahead rapidly; the immigration is something enormous, consisting mainly of Italians and Spaniards, who are at once drafted into the “camps” to take up land in the colonies, or work on the “estancias” or cattle farms.

The luxury and wealth of the River Plate is concentrated in Monte Video, Buenos Ayres, Rosario de Santa Fé, and Coriova, and these cities are amply provided with all that wealth can bestow. Outside these are immense tracts of “camp,” covered with cattle farms, with here and there the nucleus of a future city, but where, for the present, “Buenos Ayres” should he depend on retouching alone—would fare badly.—I am, yours, &c.,

J. FITZ-PATRICK, Manager.

Casa en Buenos Ayres, 126, Calle Florida, Monte Video, May 14, 1889.

A CORRECTION.

To the Editor.

SIR,—May we ask you to allow us to contradict, in the most unqualified manner, the rumour which is being so industriously circulated (for what object we do not venture to say), and which is alluded to in the copy of letter we annex?—We are, yours, &c.,

THE BRITANNIA WORKS COMPANY.

The Britannia Works Company, Ilford, London, E., July 1, 1889.

[Copy.]

THE BRITANNIA WORKS COMPANY.

Dear Sirs,—Will you kindly inform me if you have decided not to make any more Ilford plates, ordinary rapidity, as I have heard to that effect? Your reply by return will oblige.—Yours truly,

F. D. F. NEWMAN.

Rugby, Westbourne Avenue, Hull, June 28, 1889.

PLATINUM TONING BATH.

To the Editor.

SIR,—In the last number of THE BRITISH JOURNAL OF PHOTOGRAPHY, under “Foreign Notes and News,” you have given my formula of a platinum toning bath for *aristo* paper, and not platinum paper as stated by you. Please to correct.—I am, yours, &c.,

ALFRED STIEGLITZ.

Berlin, June 29, 1889.

[By the publication of this letter we make the correction desired.—Ed.]

THE EIKONOGEN DEVELOPER.

To the Editor.

SIR,—Referring to a paragraph that appeared in your esteemed JOURNAL, relating to Dr. Andresen's new developer, eikonogen, we are pleased to inform you that we have made arrangements for the introduction of this important novelty into this country, and shall be prepared to supply same in a few days.—We are, yours, &c.,

MARION & Co.

A CORRECTED FORMULA.

To the Editor.

SIR,—In THE BRITISH JOURNAL OF PHOTOGRAPHY ALMANAC I find what I think is an error in the developing formula for W. & W.'s plates—250 minims ammonia to the ounce. Should it not be 2.50 minims? Not a great difference in writing or printing, but how about the developing?—I am, yours, &c.,

T. MORLEY BROOK.

Withington, Manchester, June 28, 1889.

[Certainly; it ought to have been 2.50.—Ed.]

Exchange Column.

•• No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as “anything useful” will therefore understand the reason of their non-appearance.

I will exchange 12x10 burnisher for watch, magic lantern, or half-plate camera and lens for outdoor work.—Address, Moorak, c/o Mr. F. Hilton, Photographer, Tibshelf, Derbyshire.

Wanted, half-plate portable camera, parallel bellows, lacks, stand, and rapid rectilinear lens (first-class only), in exchange for iron foot-lathe, three-foot planed bed, two-foot driver, four speeds; telescope, three draws, O.G. one and a half inch clear, fine definition; and quarter-plate rapid rectilinear lens. Urgent.—Address, GRABORN, Photographer, Rotherham.

WE have received from Mr. W. Chambers a catalogue of photographic lenses and apparatus, from which we perceive that this gentleman, well known in London circles, has commenced business in Featherstone-buildings, in the premises so long occupied many years ago by Mr. Andrew Ross.

MESSRS. PERKEN, SON, & RAYMENT send us a letter they have received from Dr. Fridtjof Nansen, of Christiania, who says: “Having lately returned from Greenland after my expedition last year across the inland ice, I have great pleasure in now informing you that the instruments supplied by you for the expedition, namely, the three aneroids and the pocket sextant, have been proved to my entire satisfaction. Time not allowing the aneroids to be verified at the Kew Observatory as intended, I had this done at the Meteorological Institute here with the most satisfactory results as to their correctness, and although the necessarily severe usage and tests to which from the rather unexpected high altitude of upwards of 9000 feet reached, and the great change of temperature, varying from +55 to -55 Th. in the day and night, they were exposed, yet they worked admirably together, and on again reaching the sea level they differed but very slightly. The pocket sextant also, the only instrument we had for fixing our latitudinal position, proved invaluable to us and justified fully the excellent workmanship and finish.”

Answers to Correspondents.

* Communications relating to Advertisements and general business affairs must be addressed to "H. GREENWOOD & Co.," 2, York-street, Covent Garden, London, W.C.

All matters for the text portion of this JOURNAL, including queries for "Answers" and "Exchanges," must be addressed to "THE EDITOR," 2, York-street, Covent Garden, London, W.C. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.

QUINOL (Beverley).—No. 1 on your list is trustworthy in the highest degree.

F. P.—Thanks for your letter; but now that the "sweating" question has lapsed into a state of quiescence, don't you think it had better be allowed to remain so?

X. Y. Z.—The reason so little subject is included in the picture is that it was taken with a lens of too long focus. In taking interiors a wide-angle lens, for most subjects, is imperative.

N. PHILLIPS.—Negatives developed with hydroquinone resemble very much those developed with iron. Both partake more of the wet-plate character than do those developed with pyrogallie acid.

W. A. HARLAND.—If you let the products of burning gas into your drying box there is little wonder that the plates are foggy. If gas is used at all, the fumes from it must not be permitted to come in contact with the plates.

R. S. A.—About the best thing you can use for the ironwork of the studio is the Brunswick black of the oilshops. It will, however, scarcely answer for the curtain rods, as the rings will not run freely on the varnish; for these there is nothing better than blacklead.

THOS. J. FOSTER.—The work that will probably answer your purpose best is Fresenius's *Chemical Analysis*, published by Messrs. Churchill & Co., New Burlington-street. There are two volumes—*Qualitative* and *Quantitative*. They may, however, be had separately.

VERAX.—Ivory may be obtained at most fancy stationers in small sizes, but if you require it in large sheets you will doubtless have to go to the wholesale houses for it. There is no novelty in its use in photography. We have alluded to the subject many times during past years.

A. WILCOX.—You will be permitted to take photographs in the Paris Exhibition under certain restrictions. A charge of, if we remember rightly, twenty francs a day is made for the privilege. The same conditions, of course, apply to detective cameras. Using these surreptitiously entails a forfeiture of the apparatus and a fine of, we think, four hundred francs.

J. C. (Southport) writes: "In your leading article on pyrogallie and hydroquinone development you state pyro to be practically unusable with caustic alkalies except ammonia. I wrote some time ago that with the addition of equal quantities of sal-ammoniac and caustic potash as good results could be got. I might be wrong. I enclose negative (Thomas's) developed with two grains of caustic potash, two grains of sal-ammoniac, one grain of bromide of potassium, and two grains of dry pyro. Please give me your opinion."—The negative is excellent.

R. S. writes: "I wish to orthochromatise some plates with erythrosine, according to the formula given in one of the German journals. Will it do, after the plates have been treated, to rear them up on the dark room shelves and allow them to dry spontaneously? or must they be dried in a properly constructed drying box? The dark room is so arranged that it can be made perfectly dark."—The plates may be allowed to dry spontaneously. At this time of year, if the plates are treated overnight, they will generally be dry and ready for use by the following morning, unless the room is an unusually damp one.

BEX.—As some papers you have experimented with work well with the hydroquinone and others do not, it is clear that this agent does not suit all paper—that is, without modification. Most of the commercial bromide papers have hitherto been prepared specially with a view to iron development. These papers being now in the market, it rests with workers to adapt other developing agents to suit them if they relinquish those for which the paper is intended, at least until an article specially prepared for hydroquinone development is put into the market. Our experience is that hydroquinone may be adapted to all papers that we have tried, with suitable modifications.

F. S. (Bordeaux) says: "I. I would like to have the address of the makers of the freezing machine, 'Arktos,' mentioned in No. 1517 of your JOURNAL.—2. Could you let me know if emulsion makers use silver recipients or silvered copper for boiling the emulsion, for I am afraid any metallic recipients in boiling would metallise a part of the silver bromide?—3. If metallic recipients cannot be used, could you give me the address where I could find large porcelain recipients for boiling emulsion?"—1. E. M. Perkins & Son, Seaford-street, King's Cross, London.—2 and 3. Better use porcelain vessels for this purpose, although we know of both silvered brass and solid silver being employed.

NEMO says: "I have been troubled of late with curious smears on my negatives for which I could not account, and on sending a few negatives to the maker of the plates the reply was that the marks were due to the developments, but no means of avoiding them was suggested. The other day curiosity led me to take a plate out into the light for examination, and I found marks upon it just as if a snail had crawled over the film, and these marks corresponded with the smeary stains when the negative is developed. I send you a couple of unexposed plates and a negative for your inspection."—The marks are clearly in the film and are not due to the development. The plates are defective, of that there is no doubt.

S. E. BRUCE writes: "I have recently come into possession of a lot of photographic apparatus and chemicals and amongst the latter there is a bottle labelled 'nitrate of silver (fused).' It is in irregular-shaped lumps, and is of a slaty blue colour on the outside. But the lumps when broken are white, and show a crystalline fracture. The things belonged to an uncle of mine, and must be fully twenty-five years old. Can this nitrate of silver be utilised in photography—if so, how?"—The silver can be used for any purpose for which nitrate of silver is required, such as for sensitising paper. It has not deteriorated by keeping. If it be used for the purpose suggested, the solution should be made slightly acid with nitric acid.

INTERIOR.—For photographing the interior of the shop, you had better employ a wide-angle lens. The exposure will, of course, depend upon the light; but this you will be able to judge of when you see the image on the focussing screen. The use of an extending front to a camera is to permit a lens of long focus to be employed. The size of the image is not influenced by the length or otherwise of the camera, but the focus of the lens. The less light there is between the lens and the object the better. Instead of hiring apparatus specially to take a single picture of a kind you are not familiar with, would it not answer your purpose better to get some professional photographer in your neighbourhood to do the work for you? It would probably be cheaper in the end.

A. COLLINS (New South Wales).—1. By far the largest proportion of the enlargements made in this country at the present time are on bromide paper. As a rule (except for the very cheapest work) they are more or less highly finished in monochrome or in colours. The surface of the rough paper is admirably adapted for working in pastel or crayon. Some of the best houses here are working bromide paper almost exclusively for their enlargements.—2. The wet collodion process is rarely used now except for copying, and then chiefly for photo-mechanical purposes.—3. Detective cameras vary in price, from 2/ 10s. upwards.—4. A large proportion of the highest class work is printed by the platinotype process, but albumenised paper still rules supreme. Thanks for the pictures; they are charming views and well selected.

PUZZLED writes as follows: "I have been trying the quinol developer (Thomas's formula) on Ilford plates and Morgan & Kidd's bromide paper, but fail with both. The plates develop well enough at first, but when detail is well out they veil over, and after fixation, looking at the back, seem an opalescent blue, particularly in the parts of the picture where the deposit is thinnest. On the film side there appears a metallic lustre, particularly round the edges. This last seems a yellow stain when viewed by transmitted light. The paper in the vast majority of cases comes out covered with spots, as if sprinkled with black pepper. I have tried varying the proportions of the solutions, also diluting with water, but with no better success."—Perhaps some of our readers who have experimented in this direction will give their experience.

BROMIDE writes: "Can you suggest to me any restrainer to prevent collodion-bromide fogging under the developer? Some years ago I was quite successful in developing enlargements on paper, &c., coated with collodion-bromide. Recently I am quite unable to do so without their fogging, even where the paper is covered with a mask. I can succeed when a print is made direct in the printing frame, but when I make an enlargement the whole fogs. When I was successful it seemed as if it was not possible to go wrong; but with whatever care I use I cannot go right. With gelatino-bromide I cannot fail—all is so easy. If you can suggest any means of preventing it I shall be much obliged."—There is no better restrainer than a bromide. Were it not for the fact that satisfactory results are obtained by direct printing, we should have suspected the emulsion was at fault. As it is we suspect that the paper gets fogged by light during the exposure in the enlarging, or during the handling of the paper.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting of this Club, July 10, 1889, will be on *Photographing Lightning*. Saturday outing at Loughton.

ON Thursday, the 11th instant, Mr. Thomas Scotton, of Derby, will read a paper and demonstrate the working of the ferro-prussiate and cognate methods of iron printing at the London and Provincial Photographic Association.

NORTH LONDON PHOTOGRAPHIC SOCIETY.—The outing of this Society for Saturday (to-morrow) will be at Loughton. The members will meet there at three p.m., a convenient train for this purpose leaving Liverpool-street Station at eight minutes past two.

PROPOSED SOCIETY FOR RICHMOND.—It is proposed to organize an amateur photographic club in Richmond, Surrey. All those in that district favourable to such a movement should lose no time in communicating with Mr. Horace S. Hopkins, Railway Hotel, Richmond, Surrey.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1523. VOL. XXXVI.—JULY 12, 1889.

SHEATHS FOR DRY PLATES.

It appears as if the question of metallic backings, holders, or sheaths in which to hold sensitive plates or films were likely to become a somewhat burning one. By a sheath (the word is, we believe, the invention, in this application, of Mr. Thomas Samuels) is meant a piece of thin metal with turned-over edges, so as to hold a plate in such a manner that no light, if it were exposed in the camera with another sensitive plate immediately behind it, would be transmitted through the film to the detriment of that behind. It is, indeed, nothing more than a plate of metal or other rigid opaque substance placed behind a sensitive plate, and having overlapping edges to retain the plate in its place.

For this very simple contrivance several patents have been obtained or applied for. The first of which we are aware was that of Mr. T. Edward Merritt, who, on August 1, 1854, obtained a patent (No. 1696) for several improvements in photographic apparatus and means of taking photographs in the open air, and in whose specification was included the identical sheath which forms such a bone of contention at the present time. We say "identical," for Merritt's sheath is both described and drawn with so great a degree of accuracy that if the specification were placed in the hands of a workman for the purpose of having one made as there described, the resulting piece of workmanship would be the modern sheath.

The object of this sheath, as described by Mr. Merritt, is the holding of a collodionised plate of glass, or a sensitive sheet of paper kept flat by being attached to a glass plate, and, like the sheath of the present time, it is described as "a small frame of tin or other suitable material," to be employed in connexion with a camera mentioned in his specification, and in which was "a dark chamber or box capable of containing any required number of prepared papers or glasses." In Merritt's "claims" this frame or *sheath* forms a special feature in these words: "Second, the construction of a frame for holding collodionised glasses in the manner hereinbefore described." This was in the old collodion times, when as yet the sensitive surfaces were either collodion, albumen, or paper.

Later down, and twenty-nine years after the previous patent, Mr. Thomas Samuels obtained a patent (No. 813, Feb. 15, 1883) for a camera with which was also connected a sheath for holding sensitive plates, and the ninth claim of which reads:—"The combination with a photographic plate or film of a protective sheath or envelope, constructed substantially as shown and described, for the purpose specified." And in the body of the specification we read:—"My invention further comprises an envelope or sheath for each plate, by means whereof the contact of the plate or films with one another when preposited in my holder, and especially when transferring or packing them away after exposure, is avoided, and the light is prevented in passing through a plate, when under exposure, to those behind

it." The drawing which illustrates this sheath is substantially similar to that of Mr. Merritt.

Still later we have two applications for patents for film carriers by Mr. Turnbull, of Edinburgh, and Mr. Bolton, of London. But into these we are indisposed to enter more fully at present than we have done by way of append to Mr. Turnbull's letter in our correspondence in this number, because, the specifications of these gentlemen not having been yet completed, we are somewhat in ignorance as to what their claims really are. But so far as concerns what we may here term the *single* sheath, Merritt's patent, which has now expired, may possibly cause such patents for a similar piece of apparatus for holding sensitive plates to rest upon an insecure foundation. What is the difference between the sensitive plates of over thirty years ago and those now in daily use? One was collodion while the other is gelatine. Supposing that litigation were to arise out of this, would a judge in Chancery be likely to recognise this distinction? Or, to put the matter on a different footing, suppose another piece of apparatus—a lens, for example—had been patented and fully described thirty years ago, would a very recent patent for the same lens be good on the alleged grounds that the former was used for taking negatives by collodion, whereas the latter was intended for gelatine negatives? We scarcely think so. Then why should there be a like distinction made in the matter of sheaths?

We well remember when Cook's patent camera was brought out that we experimented much with it during 1869-70 (for particulars see this JOURNAL of those dates). Dry collodion plates were employed, friction between the plates being prevented by a rather thick paper edging on two sides of their faces, while the light was prevented passing from one to the other by an opaque backing, which was sometimes composed of black paper, and in our own case more frequently by applying a non-actinic varnish of Spanish brown and gum water to the back. This we eventually found to be troublesome, and supplanted it by a thin metallic backing with turned-over edges. While this was an improvement, we looked upon it as such a trumpery matter as scarcely to merit any public notice; and yet one of the modern patentees could, were he so disposed, debar us the use of it, did not Merritt's patent intervene and stop such proceedings.

By all means let us have as many inventions, and even patents, as possible; but let us not quite forget those of such as have gone before.

DENSITY WITH HYDROQUINONE.

Our article a fortnight ago on the comparison of pyro and hydroquinone as developing agents has elicited more than one inquiry as to the possibility of obtaining with the latter a degree of density under similar conditions equal to that pro-

duced by pyro; while one correspondent in set terms condemns hydroquinone as incapable of rendering certain subjects with the vigour needful for special purposes, such as photo-mechanical work.

The doubts, no less than the definite statement last alluded to, are equally surprising to us, for we have always found, and have on other occasions stated, that, if anything, the tendency with hydroquinone is in the direction of over density. In the article of the week before last, in fact, we laid special stress on the peculiar power possessed, when using the alkaline hydrates, of making provision for a greater degree of density than ordinarily required; and it is in this immediate conjunction, curiously enough, that two at least of our correspondents scent the danger of feeble images. It seems probable, therefore, that some serious misapprehension exists as to the precise conditions necessary for obtaining density.

The suggestion is made that, looking at the increased energy of the action of the caustic alkalis, the natural tendency will be to produce thin, delicate images full of detail, and in the case of even slight over exposure, the class of result formerly recognised colloquially as "burnt up." To this we can only reply, that judging hydroquinone upon the same lines as pyro, the inference is, perhaps, only natural; but that is just what we desire to impress upon our readers they ought not to do. The sooner they will thoroughly recognise the fact that the two developers are essentially different in their general style of behaviour, no matter how nearly similar their ultimate effects may be, so much the sooner will the two find their proper relative positions, and the anomalies and discrepancies in practice with hydroquinone cease to be heard of.

We long ago pointed out the fact that hydroquinone will bear the addition without injurious effect of far larger quantities of alkali than is the case with pyro. We have also described the difference in its behaviour in the presence of restrainers, such as alkaline bromides, and such substances as sodium sulphite, which in the case of pyro is variously judged in that capacity. In fact it is, we think, generally recognised that such additions, though practically essential with pyro, are not so with the newer agent, though for various reasons it may be advisable to use them in practice.

Now it is only by the full recognition of these facts, and their practical application, that hydroquinone can be made to yield results that are at all comparable in regard to quality and general convenience with those of pyro, and this is more especially the case in connexion with the question in dispute—that of density.

Under normal conditions, that is, employed in "plain" solution, or with no further addition than the alkali, hydroquinone gives images of great beauty and delicacy, entirely free, except in the case of serious under exposure, from all fog or stain, such as would be almost inevitable with pyro. But this beauty and delicacy are accompanied by a strong tendency to thinness and poorness of deposit; in other words, a difficulty in obtaining density, which is not materially affected, as in the case of pyro, by increasing the strength of the solution used. Used in this manner, the only thing that can be claimed in favour of hydroquinone is that it works without fog.

By simultaneously increasing the strength both of hydroquinone and of alkali a heavier deposit is produced, but it is not of the character that leads to vigour and contrast; it is, in fact, density, not intensity. The increase of the opacity of the high lights is accompanied by a similar and perhaps proportionately greater effect of the same kind in the half

tones and finer gradations, the whole image being pervaded by a sort of veil, not of the nature of "fog," but sufficing to give additional "harmony" to an already too "soft" picture. The ultimate effect is, indeed, simply to lengthen the time occupied in printing, without in the least improving the character of the result.

When, however, we use an addition of bromide, especially if accompanied by a sulphite, the behaviour of the developer is entirely altered. The first and most noticeable feature is the greatly protracted time required, not only in starting, but in completing the image. This is accompanied by greater clearness in the shadows, and the sum total is a strong tendency to the production of harsh results.

To overcome these, recourse may be had to one or both of two expedients, either of which will, except under proper conditions, only aggravate the evil. To increase the exposure or the proportion of alkali in conjunction with pyro development is usually tantamount to producing greater harmony and softness in the resulting image. Either remedy, however, in the case of hydroquinone, acts primarily in a contrary direction, namely, in the production of greater density and contrast, apparently for the reason that the action of the restrainer is greater proportionately on the shadows of the picture than on the lights as compared with pyro. The presence of bromide permits the use of a far larger quantity of alkali without fogging or veiling the half tints, and with this increase the density obtained is constantly augmented, so that the general tendency is to push forward the lights without a corresponding effect upon the finer details.

If the development be continued long enough to bring out the tardy half tints, the probability is that such a degree of opacity on the lights will result, that the negative is of little use for any but photo-mechanical processes, and then not for half-tone subjects, as the shadows will be too feeble.

The proper way to proceed for ordinary half-tone negatives is to keep down the proportions both of alkali and restrainer, and to exercise patience. Where ultra density is required, as for line work, then both may be increased almost *ad libitum*, and we believe no method of alkaline development will then give greater opacity.

So far we have alluded to the employment of the carbonates. If these be replaced by the hydrates, the effect is certainly an increase in the energy of the solution, but it is chiefly confined to its rapidity of action. The hydrates, in fact, seem to relieve hydroquinone of a great portion of its abnormal sensitiveness to the *retarding* action of restrainers, and to place it more on an equality with pyro. But the same peculiarities remain, namely, the capacity for using large proportions of alkali, and the disproportionate effect produced upon the lights and shadows, the property, in fact, of giving increased density with increase of alkali. By varying the quantity of restrainer this may be so varied as to add to or decrease the contrast, and so by judiciously ringing the changes any desired effect may be obtained, and with the same facility as with pyro, though with a far greater degree of density than the latter.

A SUGGESTION TO PLATE MAKERS.

It is by no means early in the day to make a suggestion to plate makers which it is matter for wonder that it has never before been carried out. It is, simply, that every individual plate should be branded. The manufacture of gelatine plates is now a business of commercial magnitude, and that hundreds

of thousands of pounds' worth of plates per annum should be sent into the market, in the direct name of those who produce them, each make having its own distinctive peculiarities of working, and that not one of them is branded or marked to distinguish it from another, seems neither more nor less than an absurdity. If the plates themselves possessed peculiarities of appearance that in the dark room would render recognition easy, these remarks would be uncalled for, but they do not; and few, if any, will be inclined to deny that if a dozen plates, each one from a different maker, were placed unwrapped in a dark room, the photographer does not exist who could place the maker's name on each with no more assistance than a mere inspection. It may be said that the users of the plates could mark them for themselves if they required anything of the sort; but, granted they could, there would be no pertinence in the reply, seeing that the complaint in question is that makers send out unbranded goods.

There is scarcely a photographer, who has not entirely confined his work to a particular brand, who will fail to appreciate the value of a plan which should enable him, no matter at what distance of time, to be able at a glance to know what particular plate he is working with when he unearths a forgotten boxful; or, in experimental work, has neglected to keep each kind sufficiently apart.

The need for branding is by no means confined to the amateur, for the professional who has to depend upon other hands than his own for filling his slides with plates, or for putting aside for development plates that have been exposed and are awaiting the bath of pyrogallol, is in the same category. How very pleasant for a dozen double slides to be charged, say, one half with quick and the other with slow plates, and through stress of weather or other circumstances kept unused for a few weeks, and then on the day they are to be used for the photographer-in-chief to be told that his assistant has mislaid his memorandum, and can't be quite sure whether the first twelve or the last are the quick plates—he knows it is one of the two! Or, again, on another occasion, when during press of work two lots of plates are put into a grooved box with a slip of paper between to separate the kinds, and the box and its contents are forgotten for a while, how very pleasant the effort to try to remember whether those to the right or those to the left were a particular kind wanted! It is useless to multiply examples; almost every photographer could supply them, and must, at some time or other, have suffered from the effects of his plates being "mixed," and maker A's plates undiscoverable from maker B's, though at the time he is possessed of a craze in favour of A or of B. Again, in the anxiety for fame it is quite permissible to imagine that when a particular negative is in question, say in competitive exhibitions, it should be easy to ascertain unmistakably by whom the plate was made.

We have said enough to show that we are fighting no imaginary grievance, it only remains to point out a remedy. The first idea that would naturally occur would be to mark or scratch, with a diamond or otherwise, some name or device on each glass before or after being coated; and there is no doubt this alone would be a step in advance. But in the dark room, which in so many instances are still merely dark dens, the labour of finding, and then of reading, the marks when found would rob the assistance of most of its value. Still, assuming that the back of the glass, and not the film itself is to be branded, it is obvious that either paint or printed label would be far better. Paint would have the advantage of being capable of application in such a manner as to be permanently

attached, unless strong friction were used—spirit mediums might be employed, and then the drying would be so quick as not to interpose with the speedy storing of the plates. It is true, labels might be attached by means of chrome alum or gelatine solution, and so be in little danger of washing off, but it is probable that preference would be given to a "painting" process. There would be a great advantage in a label, inasmuch as when it was desired to, as some photographers prefer, write a memorandum of subject or exposure on each plate upon removal from the dark slide, the maker's label might be left partially blank for the purpose of making those notes often found so useful.

Painted marks might be put on by indiarubber stamp, by stencilling, or by any other process found most easy and expeditious. The chief point to decide would be the form the device was to assume. The method likely to find favour with the makers would be to put their own names on; but it is by no means the best plan. What is wanted is a sign that could be read at a glance in the dimmest of lights, and this would not be the case with a maker's name. Of course, a capital initial letter might be used; but what would be far better would be a series of geometrical forms, each maker to announce his as chosen. There might be diamonds, squares, triangles, stars, circles, parallel lines, crosses; and these, again, hollow, solid, or combined. If they were made large enough they could receive pencil marks in lieu of labels for notes or memoranda of exposure.

The subject ought not to need more expounding; we have made a suggestion which we consider of great value. Let the manufacturers of plates consider it and put it into practice. We trust that before another year comes round there will not be a plate on sale which does not tell its own tale by marks on its back, "who made it and when."

THE friends of that *quondam* eminent photographic amateur, Mr. Russell Manners Gordon, who was at one time so well known in London circles, will be pleased to learn that, having succeeded to an old family title, he is henceforth no longer Mr. Gordon but *Le Vicomte de Torre Bella*, a singularly mellifluous title, by the way. In course of a conversation with *Le Vicomte*, who is at present in London, we learn that, although he keeps himself *au courant* with photography, he has practised it but very little since he took up his residence in Madeira, owing most probably to the lack of suitable subjects in that sunny island. But on a recent visit to the French Exhibition he has been so much struck by the beauty and efficiency of some of the English cameras there displayed that the old love has asserted itself so strongly that he will be induced once more to enter the field he had so reluctantly to give up when called away to superintend his vineyards in Madeira.

PROBABLY at no period of his life has the Shah had so many photographs of himself taken as have been secured during his present visit to Europe, particularly during his stay in this country, for nowhere, we imagine, is instantaneous photography, with detective cameras, so largely practised as in England. And wherever the Shah has been there was no dearth of detective cameras. The Eastern potentate himself takes, or used to take, a great interest in photography, and on his previous visit to this country amongst his *suite* was his chief photographer. Whether this official accompanies him on the present occasion or not we are unaware. It is tolerably certain that there is not now the same rush amongst photographers to obtain sittings from our illustrious visitor as there was on his previous visit.

WE remember an amusing circumstance in connexion with the Shah's former visit, which exemplifies the freemasonry that exists, or at least did exist, for we fear the feeling is somewhat dying out of late years, amongst photographers. A number of the Shah's retinue

visited a studio in Regent-street, and sat for portraits of a somewhat large size. After the last sitting was made, and while the negative was being developed, the interpreter left the studio to make some arrangements in the reception room. When the photographer emerged from the dark room, by signs and gestures an unmistakable desire to see the negatives was manifested. The artist tried to impress upon the sitters that they could form no opinion from the negatives; but as he could not speak Persian and they could not understand English, the explanation, as might be imagined, was not altogether satisfactory. Ultimately one of the negatives was produced, the photographer still retaining it in his own hands for fear of injury, till one of the party stretched forth his arms, with two fingers distended to take the negative, in such a manner that the artist at once recognised a brother in the craft. Each negative was then handed out without further demur, and were as jealously guarded by the Eastern *confrère* from touches by the others as they would have been by the photographer himself. Smiles and nods, and a cordial greeting at parting, showed that these two men understood each other perfectly without the aid of an interpreter.

PHOTOGRAPHS of the interior and the grounds of the Paris Exhibition are of course interesting *souvenirs* of a visit, more particularly if they are taken by the visitor himself if he happens to be a photographer. In most English exhibitions the sole right of taking photographs is generally sold to some one individual or a firm, and no one else is permitted to use a camera within the precincts of the show. At the Paris Exhibition the Executive have proceeded on different lines, and instead of selling an exclusive right, are allowing any one to take pictures within certain hours, and on payment of specified fees—so many francs per day or per week, as the case may be. Hence photography at the Exhibition is open to all. Whether as a commercial speculation this answers better than disposing of exclusive privileges remains to be seen. Exclusive rights are usually looked upon as a monopoly, but here the arrangement has a decidedly free trade character.

It did not take the authorities very long to discover that photographs were being clandestinely taken in the Exhibition. This, of course, was accomplished by the aid of detective cameras. The Executive are now, we are informed, fully on the alert for these, however well they may be disguised. A gentleman recently paid a visit to the Exhibition with a Kodak and made some successful exposures. But he was more than once an object of suspicion by the officials, and he is scarcely likely to repeat the experiment. The penalty for taking photographs is, we believe, a fine of some four or five hundred francs and forfeiture of the apparatus. Although the penalty is heavy, and the inconvenience of the loss of apparatus is great, we have little doubt but that some photographs will yet be taken without the regulations being complied with.

CLEARLY the question of dark rooms at the different Custom Houses, raised in the House of Lords a few weeks back, is not to end in becoming a dead letter, as some predicted it would. In the House of Commons one day last week another question on the same subject was put by Colonel Cotton, which elicited the reply from Mr. Jackson that definite instructions had been given to the officers of the Custom House as to the proper examination of undeveloped dry plates; and that he would take care that suitable accommodation was provided at the various Custom Offices for the examination. This assurance will be hailed with satisfaction by every travelling photographer.

It is to be hoped that the illumination provided will be arranged under the supervision of some competent person, so that the light is above suspicion. The ideas of Custom officials, who may be ignorant of photography, as to what is a suitable light, may possibly not be in accord with those of the photographers who have to submit their plates to it.

From the *Journal of the Society of Arts* we perceive that a medal of the Society has been awarded to Mr. Conrad Beck for the paper recently read there on the construction of photographic lenses.

It would be interesting to know how many of the pictures shown at the different exhibitions now open in London—not excluding the Royal Academy itself—are indebted to photography. In landscape painting the artist frequently employs a photograph to assist him in his work, the same with *genre* subjects—the models often being photographed in the first instance, while in portraiture a very large proportion of the work is executed—in some instances almost entirely—from photographs; and all this without acknowledgment. Indeed, some of those painters who utilise photography the most never fail to decry it whenever they have the opportunity. There is no question that photography has been the means of improving art, and particularly is this the case in portraiture. At one period photographers looked to painters for their poses, hence, at one time, the universal column and curtain, or the table and book. Now the case is reversed, as the different exhibitions testify.

ECHOES.

As the first outcome of the recent mention in Parliament of the difficulties experienced in passing dry plates through the Custom House, I see it announced that instructions have been issued that a "suitable dark room" is to be provided at all the chief ports of entry for the proper examination of all packages claiming to pass as photographic plates, but which may be suspected to contain matter of a different character. This is, so far, most satisfactory, but I cannot help feeling some doubts as to the complete feasibility of the scheme, at least so far as it is likely to be carried out.

In the first place, the establishment of a "suitable dark room," in the strict and accurate sense, at all our out-ports, means a considerable expense, for which the revenue could expect very little, if any, direct return. A photographic dark room, if it is to be of any practical use for its legitimate purpose, and always available when so required, can scarcely be adapted to any other purpose, and will therefore necessarily be something of a "white elephant." Officialism will scarcely recognise the utility of setting apart a specially fitted room to be held sacred to one particular purpose, and to be used at rare intervals during the greater part of the year, and only by fits and starts during the holiday season. The chances are that the dark room provided will be anything but "suitable" in many cases, and the lot of the travelling photographer who is compelled to utilise it will be worse than ever. We have it on the authority of Lord Salisbury, that on at least one occasion a Custom House officer acted, in the matter of photographic plates, with more than ordinary stupidity, and that, as a class, those officials cannot be expected to be more than human. We may, therefore, fully expect that in the future, when an unfortunate peripatetic camera man falls in their way, they will "take it out of him" by forcing him to use the room provided for him, and to test its safety and suitability at the expense of his plates.

On the other hand, it is just possible that the mere issuing of the order referred to may act beneficially for the photographer by impressing upon the mind of the average "searcher" that sensitive plates really have an actual existence, and are not the mere invention of ingenious contrabandists. The knowledge that an official dark room is *supposed* to exist may suffice, perhaps, in the official mind as a check upon attempted smuggling of small trifles under the excuse of "dry plates," and the nett result will, perhaps, be that matters are rendered generally smoother all round.

Apròpos of the remarks made a week or two back on the proportions of gold and silver relatively in photographic residues, and especially of the effect produced upon those proportions by the *tone* of the prints, I am inclined to question whether the colour, *per se*, has much to do with the matter. The strength of salting of the paper would, I fancy, prove a far more powerful factor, for a "red" print from a suitable negative upon a heavily silvered paper might contain a far larger proportion of gold than an absolutely blue image printed from a thin negative on a paper poor in silver. In addition to that, the more heavily salted the paper is, and the stronger the silver bath employed, the further can the toning be carried without producing unpleasantly cold tints, so that, independent altogether of colour, a strongly salted paper is likely to carry a larger proportion of gold. Some few years back it was stated by Mr. W. K. Burton that the

silver image upon albumenised paper may be *totally* converted into gold without robbing the print of its warm tone, though I must confess that I was not impressed with the infallibility of the arguments brought forward in support of the total conversion. Still, if the latter result is anything like approached, and a brown tone remains, what becomes of the colour test and the relative proportion of gold and silver mentioned in the paragraph referred to?

A very practical paper on a very commonplace subject was that read by Mr. E. S. Worrall before the University College Photographic Society, and some of the author's remarks are worthy of being reprinted in book form and carried in place of the usual "exposure tables." These I have always held to be unreliable, and in one sense far worse than useless, for in the hands of a beginner they establish a confidence which only confirms him in error, and prevents his gaining that real knowledge of exposure which careful experience alone can bring. I have known two distinct cases in which beginners have relinquished photography thoroughly broken down by the constant failure engendered of too implicit confidence in "exposure tables."

"Tables are useless unless they deal with constant conditions and quantities," says Mr. Worrall, and that just precisely hits the nail on the head. Again, he says, "I do not see how these (exposure tables) can be an unfailing guide to us unless used with a perfect actinometer, and this, I believe, has still to be invented." Quite so, for in my own view any form of actinometer I have yet seen is, when applied to landscape purposes, of as little value as the tables, since it leaves all the conditions except the aperture of the lens and the strength of the light entirely to the judgment. It is of no earthly use arguing, as many have done for years past, that they have got on better with exposure tables and actinometers than without. It is no proof of anything except that they are able to use some judgment, and that, naturally, with at least one extra condition fixed, that judgment can be more accurately applied.

Mr. Worrall also touches on another pet theory of mine when he says, "The more rapid the plates the less the latitude of exposures." So far as the chemical side of the question is concerned, I think few will deny that this is a fact—at least, with the general run of plates. I do not mean to say that it is a matter of necessity that a very rapid plate should not possess *proportionately* as much latitude as a slower one, but practically it does not. But there are those who, setting on one side the chemical part of the question, will argue that it is as easy, to put it as one writer did some years ago, "to err proportionately" with a plate requiring a fractional part of a second's exposure as with one requiring several seconds. This seems to me a ridiculous contention, for, even granting that the *absolute* exposures required with each are known, the mere mechanical operation of exposing to a minute fraction of a second must necessarily be the more difficult. However, on such points as these it is of little use arguing with enthusiasts; but I may say that two of the strongest opponents of my view in this matter are practical photographers of the very first class—men, in fact, whose *experience* enables them to succeed where others would fail signally. It is scarcely fair, then, on their part to entirely ignore the "personal equation."

In reading Dr. Huxley's remarks before the Birmingham Photographic Society on the subject of platinum printing, it seems to me that gentleman holds views which differ very materially from those in general vogue. He says, "A negative from which it was difficult to obtain a silver print would yield by proper treatment a good platinotype." This is entirely contrary to anything I have previously heard or experienced, for I, with many others, have always believed that a vigorous negative with clear shadows was necessary in order to get really good results. It will be interesting, therefore, to know if other practical platinotype workers find it possible, by varying the strength of the sensitising bath, to adapt the process to negatives of different qualities and characters. This is certainly the case to a marvellous extent in the carbon process, and to a much less degree in silver printing, but I have not found any practical advantage accrue from the application of the system to platinotype.

I think, perhaps, the context explains that the description in Mr. Ernest Seyd's paper of "ferricyanide of potassium" as "yellow prussiate of potash" is either a slip of the pen or of the printer, but such accidents are frequently very annoying to beginners in any process, and should be, "when found, made a note of." Let it be

remarked, therefore, that the yellow prussiate, which I believe is intended, is the ferrocyanide.

A similar "slip" occurs in the developing formula given by Mr. Paul Lange in his demonstration of enlarging at Liverpool, in which "ammonio-bromide, 40 grains" forms one of the ingredients. Ammonio-bromide of what? I presume ammonia-bromide is meant, but why not give it its proper name, "ammonium-bromide?" Our general system of nomenclature is excessively slipshod, and matters are by no means improved by the introduction of a large number of bastard expressions of purely photographic origin, or, rather, purely the invention of photographers.

JUNIUS.

COLOURED PHOTOGRAPHS.

II.

As it is always the *finished work* that has to stand the brunt of criticism, to possess the merit and value, if any, we must not shut our eyes to any consideration that may be necessary or likely to help us in working out the same. There is no absolute necessity that our thoughts should be wholly given to the numerous ways of applying colours to photographs or to conclude that the perfect photographic base be given to us. No, we should aspire to be able to produce it, or at least aid, by our artistic knowledge, in its production. Why should the photographer be considered less than the artist, or even colourist, when discussing portraiture (coloured) on photographic base? To do so would, I think, be a very grievous mistake, and one into which I hope our egotism may never lead us. The temptations are many, but we must overcome them.

There is a considerable tax upon the art knowledge of every photographer or artist who produces a picture wherein the full or three-quarter figure is represented. At times, too, one or other may have most awkward groups to pose, and it is only at the cost of much labour and thought, combined with artistic feeling, that a successful picture will be secured. Some of the most awkward groups I have seen have been successfully tackled by a gentleman whose studio is situated within a radius of about one hundred miles from Whitby, and I feel sure, if we had his opinion on the subject, he would tell us that nothing but thought and his natural artistic feeling enabled him to make successful pictures of many of them.

It is in this kind of work (groupings and full or three-quarter figure subjects) that an operator has scope to exhibit his skill and knowledge to completeness, for here he has the posing of the head, or heads, the arrangement and artistic disposition of needful accessories and various draperies. Great judgment, too, is required in the arrangement of the light, as all the delicacies of light and shade are dependent upon careful adjustment of the same. In groups, too, a general knowledge of the rules which apply to composition will be found of invaluable help.

By this, however, I do not wish it to be understood that there is little or no knowledge required for the successful posing of a bust, or that any one can place a sitter down in a chair and dash off a successful portrait. Of course, such may be done by accident, but it is unsafe to trust to such a help. There is a deal of artistic knowledge and fine feeling required to pose a head in such a way as to impart importance to it, and, at the same time, endow it with intelligence and life. It may be the very *least* turn of the head that does it, but therein lies the artistic feeling that appreciates the want and invests the portrait with artistic merit. It is this feeling that lifts the artist's photography above that of his less favoured rivals, be it through ignorance or carelessness. To bear out what I say, I may state that I know several photographers (successful London ones) who make most excellent pictures when they have the entire figure at their disposal. They show consummate skill in lighting, a keen artistic judgment in the adjustment of accessories and draperies, and yet give them a head to pose and their pictures are to a degree ordinary. To colour such a bust of course an artist would have to endow it with life; an ordinary colourist would leave it (although coloured) as it was before, lifeless. Naturally they are more like the people coloured than uncoloured, but they will always bear a strong family likeness to the plain photograph, for they lack the artistic touch and feeling which alone can raise them to the dignity of being *portraits*. It would not be allowable to mention names in these papers, but there are two or three London photographers whose works (head and shoulders I speak of) I always find pleasure in contemplating. The artistic feeling possessed by the operator is visibly reflected upon the faces of his subjects. When I cite London photographers, don't let any one run away with the idea that I place London before the provinces. In a business way the London work that passes through my hands is

really not to compare with that which comes from the *provinces*, speaking generally. I do not feel capable to judge whether press of business or lack of knowledge is responsible for this, but if I were allowed a free selection of fifty photographs I have not the least doubt I would choose from forty to forty-five from the studios of provincial photographers.

Another point to be kept in view is that a *portrait* should also be a *picture*. We must, therefore, try to settle in our own minds what is and what is not a picture. It does not follow that the reproduction of an object, or the truthful delineation of a face, granting the same to be a likeness, will constitute a *picture*. No! A really good *portrait*, to be entitled at the same time to be called a good *picture*, can result only when the subject treated is represented under such conditions of position, general appropriateness of surroundings, light and shade, &c., as will endow it with character and expression, and at the same time lend to the general pictorial effect.

The time for thought is at the *beginning*; consequently, we must hold the operator responsible for much. This because our work must follow on his lines. It is well understood that he is hampered by many difficulties, and has not the same control over his subjects that an artist has; still there is much that he can do. He can select his positions, also control to a very great extent his lights and shades, and thus secure the most pleasing and characteristic lines and features in his sitter. Judgment may be shown, too, in the selection of accessories and their artistic arrangement, they often helping to hide natural defects which might otherwise mar the beauty of a work. Tone or colour may be secured by their artful adjustment, also balance; but care should be taken to keep them subdued lest they interfere with the importance of the figure, whereas they should lend artistic simplicity, harmony, and a feeling of breadth and airiness to the finished picture.

When starting a portrait, especially full-length, it naturally strikes one that the first point to be fixed upon is *position*. To decide this it should not be looked upon as a light matter. Upon our success in this regard depends the character of our picture, as well as the general pictorial effect. Even when this point is settled there is another to consider, the position our subject will occupy in the picture itself. Looked at casually this may not appear of much moment, but it is, and may be of vital importance. A figure, I may safely say, should almost *never* be placed in the exact *middle* of a picture. I do not think there are many positions more formal or destructive to pictorial effect. I have known cases, such as soldiers' portraits, where they have looked all right in the centre of the picture, but such form the exceptions that prove the rule. Even in these improvements might be made by placing them to better advantage. As a general rule it may be taken that there should be more room in *front* of the subject than behind. The contrary might suggest that, on slight provocation, the sitter might walk out of the picture, and such is not a pleasing effect. If a lady have a *train*, say in Court dress, we may find we have to modify the above, but much may be gained in the skilful adjustment of this portion of drapery so as to enable us to carry out our rule. This rule will be found, if anything, more important as regards top and bottom than it does to the sides.

By the position we give our subject in this regard we fix his height. If the head be near the top it will suggest that our sitter is tall, if low down the opposite will result. This may be illustrated by an incident which occurred in a West End studio some little time back. It is supposed that all the officers and troopers in the Household Cavalry are "*all very fine and large*," but it is not so. After the war in the Soudan orders were given to make the swords longer, and one day at the studio an officer came to be photographed, who was (I flatter him when I say it) low sized—I feel sure if he had to have drawn his sword in a hurry he could not have succeeded without a life-and-death struggle, or the help of a step ladder—still an imposing picture was made of him. He was placed well *up* in the picture and a *low* pedestal placed beside him, which by contrast gave him height; then when the picture was being trimmed for mounting it was cut comparatively near to the head, and when on the card gave the idea of a man valuable to his Queen and country. Although all this can easily be seen as applicable to full-length and three-quarter figures, one might think it did not apply to busts, but it does. Height can be implied, and when in a bust the face is profile or three-quarter there should be more space in front of it; if, however, the face be absolutely full, without being in the least inartistic, it may be placed equidistant from either side.

It is possible to place the human figure in almost limitless positions, but care should be taken to secure one that will suggest ease, grace, and character—a result not too easily obtained. An object or purpose should be reflected in the position selected. This does not mean that

the sitter must necessarily be engaged in any particular occupation. Great attention must be paid lest the expression of consciousness of being photographed, or that of complete vacancy, should be depicted upon the sitter's face, as such would be ruinous to our picture.

In ladies' portraits there are many positions which impart action and intention—reading letters, arranging flowers, or looking at a picture, &c., at the operator's option. These occupations for gentlemen's portraits would not be quite so felicitous perhaps, but there are others at our command. Even that conventional "*book in the hand*" can be used to advantage if skilfully arranged so as to give expression and purpose.

Many approve of complete repose in a picture, but it should be, if I may so say, "*intellectual repose*." A danger that lies close at hand is the appearance of absentmindedness, fatal alike to a good portrait and picture. In all cases avoid straight lines and angular positions, at times more troublesome than appears on the surface. The human figure in a "*bolt upright*" position is not at its *best*, although, perhaps, at its *highest*. In a man it is devoid of grace (if we can ever boast such a quality); in a lady it is awkward, if not absolutely offensive. It is, therefore, advisable that the figure should lean slightly against some article of furniture, such as a high-backed chair or screen, &c., thus giving a slight inclination, and lending itself to curved and flowing lines both for figure and drapery.

In a standing figure there is more repose suggested by resting the weight of the body upon one foot rather than both. To rest the figure upon both feet equally, and at the same time secure ease (elegance is out of the question), is a task I do not advise any one to tackle.

In a question of composition, always bear in mind the most beautiful and perfect effect to be arrived at is *simplicity*. Over elaboration mars the beauty of a portrait, and detracts from its artistic excellence. Examine the works of our most famous portrait painters, and note the tendency of all the lines, the extreme simplicity and unpretentiousness of the colouring. Yet what beauty and effect! See what a balance there is in the entire picture. In the upper parts there is atmosphere, and in the lower weight and solidity, conditions most desirable in all portraits, whether in colour or plain photography.

REDMOND BARRETT.

CARE.

THE careful photographer is careful of his belongings, and whenever you see a man scrupulously fastidious about the condition of his camera and lens, it is an outward and visible sign that he will be careful about his work generally. The reasonable inference is, that he will be tolerably successful in anything he may give his attention to. Habitual care shows itself in everything a man does, and in quite as pronounced a manner as does habitual carelessness, when we find force used instead of dexterity—lenses dropped and focussing screens broken, &c., a sort of rough-and-ready treatment all round, with a supreme indifference to the results. The work of such a photographer is generally defective, no matter how artistic his pictures may be. Careful manipulation and artistic judgment must be combined to produce thoroughly good work, and when we see it we know where to find the successful man. There are, of course, no rules without exceptions, but careful men and careful work generally go together. If we look behind the scenes, we shall, nine times out of ten, find the skilful professional, whatever his profession may be, also skilful in many other ways than the one with which the public associate his name. I believe all, more or less, possess a certain aptitude for mechanics, draughtsmanship, or a general all-round inventiveness; the fact of the exhibition of exceptional skill in any particular direction that requires special manipulative power indicates that a general all-round ability exists, that would be exercised in some form or another under any circumstances, which the bias of the possessor has turned to some particular line more congenial to himself than others.

To be a skilful photographer, scrupulous care and exactitude is required in this as in other things, and this habit of carefulness will include and extend to everything taken in hand, from the setting up of the camera to developing and finishing the negative. By the term photographer I do not mean the man who does little more than expose his plates, and, perhaps, develop them according to some special formula, from which he never intentionally deviates, but one who understands the process from beginning to end, and, if necessity should arise, could prepare all his requirements unassisted, and do it well. There exist brilliant geniuses, who, being thoroughly capable, seem to delight at being ostentatiously careless, and making an immense amount of waste without an adequate return. This class is generally found among the gilded youths of the period, who,

as soon as they have made themselves masters of their hobby for the time being, throw it up, and are equally hot on something else, to be relinquished in its turn; they are, however, most frequently a terrible infliction to those about them.

In defining the term, care of apparatus, it may be said to be protecting it from injury, and never using force when knock will do infinitely better. Good apparatus will with care last a lifetime and look well, but to keep it so, it is necessary to keep it dry and scrupulously clean. On returning home from an outing all dust should be removed with a brush or cloths, and the woodwork rubbed up with a waxed polishing flannel, then, after dusting out the case, replace it and set it aside in a cool dry room till again wanted. The dark slides should be kept in waterproof bags lined with flannel, and when the plates are taken out for development not laid down on a wet table or left knocking about open till wanted again, accumulating dust and damage. Dry storage is a wonderful factor in the preservation of cabinet work. If the camera or slides get damp the probability is that they will stick when used, and considerable strain will be given to the delicate woodwork, both in placing the slides *in situ* and in removing them; the shutters may also be difficult to open and close, to say nothing of the danger of shifting the camera with the force that has to be exercised, and so spoiling the picture. "Keep dry" is a rule never to be infringed; a square of waterproof material takes up very little room or weight and is very useful, not only to protect the apparatus from a shower of rain or a continuous drizzle when one is unfortunate enough to have to work in it, but will do excellently well for a table cloth when developing or blocking out light if changing plates. The leather bellows of a camera once soaked through is never so nice again, it becomes stiff and the glueing gets loosened. Warping may take place in the woodwork, not very much perhaps, but sufficient to make it less light tight than it ought to be, and the screws get rusty. The rough treatment some cameras get without becoming unusable speaks wonderfully well for the workmanship and the thoroughly seasoned material used in their construction.

Circumstances may occur when the care of the camera is beyond the control of the photographer; at such times, if possible, it ought to be packed with extra care. If on a railway journey, the leather cases usually supplied for them are very little protection, and require a wooden or wicker case in addition. Carriers are proverbial for destructiveness, and anything in the shape of a box comes in for their particular attention. More care than is frequently shown is required in moving the tripod and camera when set up for use; a leg may become detached and the whole apparatus swing round, and, if it does not come to the ground, will probably get strained and injured. Altering the position of the camera requires perhaps as much, if not more, care when at work than any other operation, and perhaps more damage is done in performing this simple operation than any other. Care should always be taken never to leave the camera or dark slides exposed in a blazing sunshine, or to place the focussing screen, when it is removable, in a place where it is likely to be kicked against or trodden upon. These little matters, self-evident as they are, frequently add to the discomfiture of the photographer when on duty. It is so easy to forget when the mind is full of picture taking, especially if waiting for some particular effect.

Lenses should have special care taken of them, and not scrubbed or polished any oftener than is absolutely necessary, then only with a soft leather and gentle friction. When out of use they should be kept in a close-fitting padded case, so that the temperature they are in is not liable to sudden fluctuations. The condensation of moisture on their inner surfaces fixing the dust that may be there is one frequent cause of dimness. A cold lens taken into a warm room will become covered with moisture, and a few repetitions of this produces a film on the lens that requires polishing off, and the less rubbing of any sort a lens gets the better. Care must be taken, in replacing lenses that have been removed from their mounts, that the thread of the screw is in proper register; if there is the slightest friction or force required more than usual it is because there is something wrong in the register, so do not use force to make it fit, but start afresh. If you are attacked by a dog, fling a stone in preference to your lens at him. In other words, always handle your lenses with the most scrupulous care, as if the slightest rough treatment would injure them, and always keep them under your own control.

Exercise care in the treatment of your plates from the time you take them out of their original packets till they become finished negatives worth keeping; care that no stray white light fall on them at the wrong time, or any light at all more than necessary; care that your dishes and measures are clean, and that your bottles are not left uncorked or unstoppered if there is anything in them; care that you have them properly labelled; care that, in making up your formulae, that the quantities are not transposed, or that, in developing, ammonia

is not added in mistake for bromide. If all these and other little cares are taken, it would be surprising what a number of good pictures would be turned out to what there are; for photographers may rely upon it, that success depends more on carefulness about many little things than the make of the camera or sensitiveness of the plates.

EDWARD DUNMORE.

COLOUR, ITS STUDY AND RELATION TO PHOTOGRAPHY; ALSO THE TAKING OF PICTURES ON OPAL CARDS.

[A Communication to the Bath Photographic Society.]

THE perception of colour by the eye tells us only of our impression of the thing, not at all the thing itself. When we speak of redness of a rose we really mean that its petals have the property of reflecting certain rays of light, and that the light produces in us the sensation of colour we call redness. It was not, however, until Newton showed that ordinary white light can be split up into many colours that it was easy to comprehend that the red colour of the rose is due to the property which it has of selecting the red, and reflecting it, while the other colours are lost.

There are two very common errors on the subject of "primary colours:" one is to suppose that Sir Isaac Newton discovered seven primary colours when he split up a beam of white light by means of a glass prism. The so-called seven colours are, as is well known, red, orange, yellow, green, blue, violet, and indigo. The ordinary colour of indigo is not pure enough to rank among these. A more correct and complete list would be—violet, violet blue, blue, peacock blue, sea green, green, yellow green, yellow, orange yellow, orange, orange red, red, deep red; most apparently pure tints are a mixture of a group of these, or four of these colours. The green of a leaf contains a small amount of violet and blue, and a considerable quantity of deep red. The orange of a certain kind is nearly pure. These tints, however, are not more beautiful on account of their purity, for exactly the same apparent tint could be produced by a mixture of several colours. *Pure colours are very rare in nature.*

However, I am not going to detain you with the mixture of pigments; it would take too much time. When white light falls upon a piece of coloured glass, some of it is reflected at the surface and the rest attempts to penetrate the glass—some of the rays succeed in getting through, and others are stopped; something, however, must become of them, for nothing is lost, *even in colour*. They are neither reflected nor transmitted, they are dissipated in the form of heat, &c. Those rays which get through have little difficulty in piercing another thickness, they have, as it were, a passport for that substance. Before the light passes through it meets with the second surface, and here some of it is reflected and retraverses the substance, a portion being again reflected at the first surface, the greater part of that which has not been absorbed passes through. In a mass of crushed glass the light will behave in this manner in passing through the first particle, and on striking the next some of it will be reflected and pass back through one of the upper pieces; some will strike deeper and be reflected through several layers; the general light reflected from the whole mass will be partly white light and partly coloured. This state of things exists in all coloured bodies—they are all more or less transparent. It will be noticed that the less transparent bodies have a whitish colour compared with those which are very transparent. It is now clear by this that in mixing paints we do not add the colours but subtract them, for the light which has passed through the first particle has in all probability to return through another of a different kind, and only that light succeeds in traversing both which can pierce both substances.

Colours are said to be simple when they are to be found among those into which white light is split by the prism. There are a large number of tints which are composed of pure colours and white; one colour remains which is not a simple colour, nor a mixture with white and black. This is purple, which is a compound of blue, violet, and red. There is a popular error, and one which it is very difficult to explain; it is that there are three primary colours—red, yellow, and blue. This theory was supported by Sir David Brewster, whose optical discoveries gave him considerable claim to be heard. The common argument is, You cannot make either of the colours by any mixture of two or three colours, while any colour can be matched by a suitable mixture of them. The fact is, that this power of producing other colours by mixture of pigments is due to their not being simple but compound colours, as I have already explained. There is, however, another colour theory, I mean three-colour theory, which is supported by the names of Young, Maxwell, and Helmholtz (no mean names, I can assure you), and this is founded not on paints, or, indeed, on any external colours, but on the structure of the eye. It has been

almost indisputably proved that there are three sets of nerves, or three processes of sensation in the eye for red, green, and blue, or violet. It is true that these three colours seem ill-suited to make by their combination all other colours, but that is because one is accustomed to think of mixtures of paints, not of colours proper. There are many ways, but they are beyond the scope of this paper, in which it may be plainly shown that blue and yellow, or green and purple, or red and blue-green, make white, as red and green make yellow. The red-seeing nerves take in the orange and yellow, and the green set takes in the yellow and blue, so that a yellow tint is known by its action on both red and green sets, in a proportion depending on the kind of yellow. When all three are equally excited the effect of white is produced. If one of these sets of nerves is fatigued by dwelling for some time on nothing but the colour which principally characterises it, it becomes less capable of being stimulated by it, and if all three sets are then given an equal chance, by looking at a white surface, the other two sets of nerves, being, so to speak, fresher in the field, have it all their own way, and give the impression of a blue-green. An example of this is well known in the form of a popular advertisement. Another instance of the fatigue and repose of the different colour perceptions is to be noticed at night. Artificial light is generally rich in yellow and red rays, and deficient in blue and violet; in fact, after dark the blue-seeing nerves being, as a rule, so little used, the others warp the judgment of the mind, and a false standard of white is set up—the standard is yellowish, but it is not as though we see through yellow glasses; the more the nerves are excited the whiter is the effect. The mind becomes accustomed to treat a full excitement of the red, a partial excitement of the green, and a feeble impression on the violet-seeing nerves as an equal stimulation of the three, that is, white; and when a more liberal proportion of blue rays is present the effect appears more as an excess of blue. Who has not heard of the blue and deathly appearance of the electric light, especially when they first see it? In time you get quite used to it, and do not notice that appearance; in fact, you like it. Many people are charmed with the electric light in my studio at Piccadilly. Lady Torrens, who was in Africa many years, said, "This is charming; exactly like the African sun." Nobody knows what a grand future there is for electricity, and nobody knows the troubles of the working of it at the present time which will make it more easy for the future workers. Well, the actual colour of the electric light is really a pale primrose when compared with the light of day, and the sun itself, which is, after all, our only ideal of white, is thought by some to be inferior to many stars in the whiteness of its colour.

Though nature is so full of colour, and it acts upon our senses with such force, and we may say it is inherent in all things, I believe the knowledge of the whole world will be found out by colour; I don't mean only the bright and brilliant colours, but the faint and dusty colours as well. I maintain, with our slight knowledge of the physical forces, it is impossible to give an explanation of colour, with its separation and contrast, union and reunion, augmentation and neutralisation, and goodness knows what. If the ox begins to rave at one colour, those who try to fathom it with its two million of tints may be excused if they begin to rave and get furious; nevertheless, let those that study colour for pleasure, let them only master one of the two million tints, and they will have accomplished something to the most complicated and beautiful subject. To others who are not so fond of minute detail, and take a broader view of the subject, let them take the relation of colour to the eye, its action upon that organ, and the action of colour on substances around in the evolution of nature; that is to say, the physical and chemical colours. The first is passing, the second may be made permanent for any length of time, and this is why, I believe, as time rolls on, the problem of obtaining permanent photographs which shall represent objects in their natural colours will be discovered. We are not going to master colour with reading a few paragraphs and doing a few experiments; it will be one continual game of chess: we shall snatch a pawn here and there, and by-and-by some genius will take a knight or bishop, but the grand difficulty will be checkmating—perhaps, after all, it will be a draw. A chemist looks upon colour as an indication by which he may detect the more secret properties of material things, but he finds much difficulty and inconvenience. Why? Because our knowledge of colour is very vague; but no doubt the very faintest tint has its chemical law, and I should say colour is rather calculated to bring to light the most delicate operations of nature. Of course, though I say this, you must consider that the ideas of men vary according to the way they approach a science or branch, for it depends upon which angle they begin at.

Now, the relation of colours to photography is like the relation of vitality to our bodies; it is the nucleus and harmony of everything connected with our beautiful art—which is the steady pioneer and

truthful recorder of nature's secrets—encircling the whole world with speaking shadows of profound interest, and occasionally recording the poetry of motion of the whole universe. There will be more poetry still when we can catch animate and inanimate nature decked in their gaudiest dress of colours just as they are, without pale yellow coming out dark, and dark blue coming out light. Violet we naturally regard as a moderately dark colour, but photography has hitherto represented it as one of the lightest—to understand this, let us, for a moment, consider the relation of photography to the three great divisions of the spectrum, viz., chemical, visual, and heat rays. Photography is essentially a chemical process, the chemical and ultra chemical rays affecting vigorously the sensitive plate; the visual rays have considerably less effect; the heat rays have comparatively none. Practically, no effect is produced when the sensitive plate is exposed to the dark-red rays. Now, the very important question which presents itself is, colour sensitisers, although some assert that the correct rendering of colour gradations is only a matter of exposure, and the so-called orthochromatic plates all rubbish—well, I only smile at those remarks, and wish the ones who make them had done a little practice in that way; as long as only a few practice, we shall not make very great strides, but let it be practised by a lot, and their experience diffused among the many, then we shall have the links accumulating, and not until then shall we advance much. The brightest conquest of the human mind is finding out the truth; with our exceedingly limited faculties we cannot flatter ourselves we know the absolute truth of many things, and if we study nature as a whole, we must take in consideration the mind of the whole human race; so in thinking we must consider our mind is a very small portion of the minds of all the human race, we shall then comprehend how the various minds that study colour consider it under extremely different relations, when, in fact, that which strikes one individual particularly will not strike another at all, because it has not yet been permitted to an individual to make a complete analysis of any one subject, for the desire which leads us beyond our boundary is always our failure. I mean that each science is so dependent upon a lot of others that you cannot draw the line, and, as a rule, one is always trespassing.

Electricity produces phosphorescent effects in the violet end of the spectrum. It may be probable that from the infra red to the ultra violet, the molecules of different things have their electrical conductivity in proportion to their position in the spectrum, and the effect of electricity and light is brought about in unstable bodies much more quickly than in stable bodies, and perhaps chemical affinity will be traced very near the light effect and electrical conductivity of the molecules, because here you can bring in *time* to help you in your researches, and what can help us more in making these inquiries than making photographic emulsions? Here you have in testing the sensitiveness of an emulsion slow towards the red, quick towards the grey or blue; but what is going on between? The word *time*, which ought to be the most important word in any science; and here we have, according to the time you are heating the emulsion, so according to the proportion of time does it take to act when we expose the sensitive plate to light, and according to the electrical condition of the alkali and acid developer so is the effect (which you can prove by *time*) of the clearness or fogging of the sensitive film. I am under the impression that chemists, as time rolls on, will value photography much more than they do at present, for the relation of photography to colour is one of the most simple and yet marvellous of nature's phenomena.

There is a light within us which cannot be decomposed to red, green, blue, &c., but a light which inspires and guides us in science to be always searching for facts and truth which only *time* can measure. Let us in the study of colour, or anything else, take the most simple things. If I take this ordinary wax match and strike it, what an immense study here! The friction you have is electricity (you must remember that is caused by the energy of my body); on striking the match then an explosion, during that time the top of the light is orange; when the flame is quiet you have yellow on the upper part, violet and blue at the lower. There are other colours if you look closely into it; for instance, there is a grey around the stem, besides the stem is brown as it burns away, and red at the top, which is the heat rays. Here you have all the colours of the spectrum except green, but we can trace it. As this match burns it absorbs oxygen and throws off carbon. Where does the oxygen come from and where does the carbon go? Why, the leaves of plants, &c., inhale the carbon and exhale oxygen, so this very wax of the match goes to form the green which absorbs certain of the sun's rays, so that life can live in the leaves, for the green acts as a shield which preserves life in the plant. I could talk for hours on a match, but I have tired you quite enough, so I'll conclude with saying photography is just the

thing to give you the power of perception and lead you closer to nature's secrets, for inside of us must be a *sense* by which we attract the fleeting scenes outside, and that *sense* has a great deal to do with dressing the outer scenes. The best element we have is the *ebb* and *flow* of reason; it sums up the history of all science which is coloured with curiosity, and you must have one to co-operate with another.

I'll now demonstrate before you a picture on my opal cards. I claim for it *simplicity*. You can print the pictures by matchlight, gaslight, or candlelight in a few seconds; the least you wash the better; you require no paper, toning, or solution. You can turn them out quicker than any other process because there is no mounting, and they are as permanent as any process we have in photography, according to my testing up to the present time. I attribute that to the finding out of hydroquinone for the last clearing effect, which was purely by accident.

FRIESE GREENE.

ON ALLOTROPIC MODIFICATIONS OF SILVER.*

As the material appears continually to change, the amount of washing needed must depend on the object in view. If wanted for analysis, the washing must be repeated many times until ferric salt ceases to come away, but no amount of washing will entirely eliminate it. After seven or eight solutions in pure water, and as many precipitations, the material is to be thrown on a filter, the liquid forced out as completely as possible with a pump, and then the ammoniac nitrate washed out with ninety-five per cent. of alcohol until the filtrate leaves nothing on evaporation. The substance at this point is still soluble, though much less so than at first. During the washing the solubility slowly but steadily diminishes, a fact rendered noticeable by less and less ammoniac nitrate being required to precipitate it from its solution.

Analysis.—The product, after thorough washing, as above described, with alcohol, was dried at ordinary temperatures or a little above, and was then reduced to very fine powder, and washed again with water as long as anything dissolved. It was then dried at 100° C. in a water bath. Three silver determinations were made:—

A ₁	97.31 per cent. silver.
A ₂	97.18 " "
B	97.21 " "

A₁ and A₂ were made with different portions of the same material; B with different material prepared in exactly the same way.

The substance, therefore, contained on an average 97.27 per cent. of silver. The nature of the residue would decide whether the material was silver with a certain amount of impurity firmly attached to it, or whether we had to do with silver in chemical combination with other elements.

The filtrate from the silver chloride in analysis A₁ was evaporated to dryness, and was found to contain chiefly iron and citric acid. The iron was thrown down as sulphide, redissolved in nitric acid, precipitated hot, washed with boiling water, and gave 0.8947. The residue, therefore, consisted of ferric oxide and citric acid, probably in the form of ferric citrate, and attached so strongly that even the very careful and prolonged washings given failed to remove them. Stronger means would be required than could be used without altering the condition of the substance. The conclusion, therefore, seemed to be justified that the material consisted of uncombined silver mixed simply with impurity.

To verify this conclusion by additional evidence, the substance was examined as to its behaviour when heated. For if any other element were chemically combined with the silver, it would only be (in view of the high percentage of silver) hydrogen or oxygen. We might have to do with a hydride, analogous to Wurtz's hydride of copper; or possibly an oxide; but not probably, as Ag₂O would contain only 96.43 per cent. of silver.

The presence of either hydrogen or oxygen in combination with silver seems to be pretty certainly negated by the action of dilute sulphuric acid on this (and the other two substances, B and C, to be described farther on). They are all converted into grey metallic silver without the slightest escape of gas. This seems tolerably conclusive in itself, and the result of exposing a great number of specimens of all the forms A, B, and C to the action of heat was equally so. As the object was to expose the fresh and moist material to a gradually increasing heat, from that of boiling water to a low red heat without interrupting the process, the following arrangement was found convenient:—

A piece of Bohemian glass tube about six inches long was sealed in the lamp at one end; the other closed with a rubber cork, through which passed a small gas delivery tube; and another tube passing into a small test tube partly filled with water, and having another tube through the cork passing under the surface of the water, thus preventing regurgitation. The material was thus first exposed for some hours to a heat of about 160° C. in a chloride of calcium bath; this was next removed, and the heat continued to low redness. Only traces of gas were evolved, and this was found to be in all of the many trials made, carbonic acid, derived from the citric acid, adhering. This treatment was repeated many times with all the different varieties of the substance, and with the same result.

* Continued from page 461.

The temperature was always raised sufficiently high to ensure the complete conversion of the material into normal grey silver, but in no case was oxygen or hydrogen set free.

It could not be overlooked that in all these trials the material had passed into an insoluble form before the silver determination was made. There remained, therefore, this possibility, that the silver, so long as soluble, might be in combination with citric acid, and that its change to the insoluble condition was caused by its separating from the citric acid. It seemed desirable that this view should be tested. As the object was to determine the condition of the silver in the substance as originally formed, avoiding, as far as possible, to change that form by attempts at purification, the only course available was to determine the ratio between the silver on the one hand and the citric acid on the other, either excluding from the determination, or else removing, that portion of the citric acid which was combined with sodium (sodic citrate being used in excess) or with iron. The first attempt was to exclude without removing it, by using Wolecott Gibb's ingenious method of precipitating the base by hydrogen sulphide, and determining the acid thus set free in a solution originally neutral. It was ascertained by careful experiment on weighed quantities of pure anhydrous citric acid that exact filtration could be made with the aid of phenolphthalein. The silver was next redissolved and estimated as chloride. A large number of determinations were made, but the method proved unsatisfactory. It was found that portions of the same material operated upon separately gave different (even widely different) results. In fact, this very discordance was in itself a proof that no stoichiometrical combination existed between the silver and the citric acid.

The importance of the matter led me to take it up again with different means, estimating the citric acid by Creuse's method. In this method the solution, after being reduced to a small bulk, is exactly neutralised (with ammonia or citric acid), is tested with a slight excess of barium acetate, and then mixed with twice its bulk of ninety-five per cent. alcohol, let stand a day, and filtered and washed with sixty-five per cent. alcohol. In igniting, a few drops of sulphuric acid convert the barium salt into sulphate, in which form the estimation is made. A preliminary trial with a weighed quantity of citric acid showed that this method gave fairly good results. I was obliged to vary the method somewhat; the precipitate of barium citrate carried down with it enough iron to render it ochrey in appearance. It was, therefore, after thorough washing with sixty-five per cent. alcohol till every trace of barium acetate was removed, dissolved on the filter with dilute hydrochloric acid (acid 1, water 10), in which barium citrate is extremely soluble and washed through. This was followed by still weaker acid, and finally with water. From the filtrate, sulphuric acid precipitated snow-white barium sulphate.

But this method requires that both the sulphates and the excess of sodic and ferric citrate shall first have been perfectly removed. The blue precipitate was therefore washed with dilute solution of ammoniac nitrate until this was effected. The necessity for this purification was regrettable as introducing a possibility of a change during the treatment. It was, however, indispensable that the ferrous, ferric, and sodic citrates should be got rid of. The material after this treatment was still freely soluble in water, to a dark-red solution. An examination of its absorption spectrum showed it to be still a true solution. From this solution the silver was first removed by H₂S, and then the citric acid was determined in the above described way. (If the silver were thrown down by hydrochloric acid, the reliability of the citric determination would be impaired.) Next, the silver sulphide was converted into chloride and weighed.

The result gave the ratio:—

1 gramme silver to .03195 gramme citric acid.

In this case, washing out the sulphates, &c., was an affair of several days. The work was repeated, reducing the time as much as possible. The material was precipitated, decanted as soon as settled, thrown upon a filter pump, and the funnel kept constantly full of ammoniac nitrate in dilute solution by a wash bottle. By using very thick paper and a powerful pressure the entire washing was rapidly finished, so that in about six hours from first precipitation the material was thoroughly washed, redissolved, and again filtered, and placed under the action of H₂S. The result was,—

1 gramme silver to .0130 citric acid.

When these relations are reduced from weights to equivalents, they become:—

No. 1.	1 equiv. citric acid to 55.63 equiv. silver.
No. 2.	1 " " 193.7 " "

indicating both that the proportion of citric acid present is variable, and that it is certainly not in stoichiometrical combination with the silver in the substance examined.

It has already been said that these solutions, before being acted upon by H₂S, were optically examined and found to be true solutions. The inference, therefore, seems to be very strong that there exists an allotropic form of silver freely soluble in water. This is a property so exceptional in a metal that I have admitted it with much hesitation. The principal arguments are as follows:—

The content of silver in the various products was very carefully, and I believe I may say quite accurately, determined. It was extremely high, always above ninety-seven per cent. As already remarked, this virtually

excludes the presence of all elements except hydrogen and, possibly, oxygen. These elements were carefully searched for; but their presence could not be detected. To suppose that we had to do with a mixture in which some compound of silver was mixed with metallic silver was not possible; for, as the whole was soluble, we should still have to admit the solubility of silver.

We have consequently to deal with a substance containing over ninety-seven per cent. of silver, and neither hydrogen nor oxygen in combination with it, the remaining two or three per cent. fully accounted for by ferric oxide and citric acid, determined as present as accidental impurity, the substance itself readily amalgamating with mercury by simple friction, nevertheless abundantly soluble in water. If I had been able to find any other explanation for these facts without admitting the solubility of silver I should have adopted it. But none presented itself.

Whether in solution it exists as a hydrate, that is, in more intimate combination with one or more equivalents of water, cannot be said with entire certainty; but the easy amalgamation with mercury seems hardly to favour that view. No means could be found for settling the question absolutely. Certainly at 100° C. all water is expelled, but this of course is not an argument. All the water is not expelled by indefinite exposure to a vacuum over sulphuric acid, but the proportion left is very small.

The material examined was in all cases as nearly as possible the same as that originally precipitated, but absolute identity could not be obtained. The purification absolutely necessary effects some change. This is shown by the colour. The freshly precipitated material dissolves to a blood-red liquid; by great dilution, yellowish red. The purified substance gives a darker red, which with dilution remains still red. Of the nature of the substances in the condition in which they were analysed I can speak with some positiveness, and these include a substance soluble in water and nevertheless appearing to be nearly pure silver.

The constitution of the lilac-blue substance at the moment of formation, and whilst under its mother water, is a matter of much more difficulty; it could not be said with certainty that it was not in some way altered in the purification. Much time and labour were spent in endeavouring to settle this point, without entirely satisfactory results, and I am at present engaged in the search for a better method.

When this blue soluble substance—purified either by washing very moderately by ammonium nitrate, or by washing with pure water, using these portions which remain undissolved after most has been carried through the filter—is brushed over paper and dried rapidly, it exhibits a very beautiful succession of colours. At the moment of applying it appears blood red; when half dry it has a splendid blue colour with a lustrous metallic reflection; when quite dry this metallic effect disappears, and the colour is matt blue. Examined with a polariser it shows the same characters as to two reflected beams of light polarised in planes perpendicular to each other that are described further on under B.

When the blue substance prepared in either way dries more slowly in lumps, the result is very variable: sometimes it is bright bluish metallic; sometimes dull lead colour, with a metallic reflection only where it has dried in contact with a smooth surface.

M. CAREY LEA.

(To be concluded.)

JACK AND I IN NORWAY.

IV.—MOLDE TO NAES.

We left Molde in a small local steamer named after the town, and in size, as I stated in my last, about half as large as an ordinary river tug; as we crept along the shore we made some exposures on the most interesting views, but the boat was so small that the vibration from the play of the engine showed a decided shake in many of the negatives so taken, no matter how quick the exposure. We were going on to Naes, a distance of some twenty miles, embracing a panorama of the grandest and wildest description, through a continuous interlacing of waters that lapped, and swished, and surged along the mountains' base, mountains that towered thousands of feet in the air majestic and grand. In many cases these mountains rise perpendicular as a wall. Sheer rock and barren of foliage of any kind, except where small trees here and there have found a home in the crevices of the rocks. Now and then the eye is relieved by patches of green grass and belts of foliage, but barren rock is the most prominent feature in this endless chain of mountains, each and all of them wearing their caps of snow. So awe-inspiring is the first entrance into these wilds that the visitor stands breathless with very wonder as he gazes upon them.

On board this boat we again met young Naes, a gentleman who came across in the *Norge* with us. Between the taking of pictures he started to amuse me by declaiming in his native tongue the patriotic poems of his fatherland, but when one only hears the sound, and fails to catch the sense, it gets to be tiresome after a little, so I told him if he could not turn it into English, that I had got as much as I could carry away, when he immediately tried the English and settled to it in something like this: "We love our country—dear native land surrounded by the sea—it is ever progressing; with affection we embrace its rugged cliffs towering to the sky furrowed and lined and worn by the sweeping storm and the lashing sea. This tempest-tossed child of a thousand homes holds our undying love, &c." To hear him orate something like the foregoing in

broken English and stopping every now and then at his best points to think out the English words was very amusing. I think as a people they are peculiarly fond of their native land.

The many little hamlets that we put in at on our way were each composed of a dozen to two dozen houses—little wooden erections dotted all over the lower incline of the hills and coming down close to the edge of the sea, where usually a little wooden pier ran out some thirty feet into the water. In the smallest of these villages there is one feature scarcely ever absent, namely, a little church with spire standing out white and conspicuous. All these places, as a rule, lie in a sheltered spot at the top of a fjord or arm of the sea, so that we seemed to be continually running out and in to these bays, for no sooner did we get out of one than we would be turning into another, and this continued all the way, our little boat looking like a nutshell floating along under the shadow of the towering cliffs. We got a good photograph of one of the most important of these stations—Nordvick—after which we came sailing round a promontory on which, quite close to us, was reared a pillar of rock on which was carved or printed an inscription. The captain told us that it was the pilot's monument. This pilot turned out to be a hero, one who had done good service to the State by misleading the enemy when in charge of his vessel and bringing him into the toils of the Norsemen. We made a picture of this monument, but the colour of the pillar was too much like the surrounding rocks to be effective.

The boat stayed for some time at Vehlungsnaes, so that we had an opportunity of taking the Romsdalsfjord from this quay. Then we sailed round the peak of land that strikes out into the sea at this point and arrived at Naes, it being but a two miles' journey between the stations. We had our traps transported to the Bellevue Hotel situated at the top of the incline on which the village is built. Here we found an obliging landlord, good food, and a comfortable house lying in the centre of an amphitheatre of hills, the snow in patches scattered here and there all round the house wherever there was a sheltered nook; crisp and hard it lay in the face of the blazing sun: in many places where we measured it it was eight and ten feet deep. In this valley, or rather flat bit of land (the word flat is only comparative), there were trees and grass and a few wild flowers. After the many barren spots we had passed it looked beautifully fresh and green.

From the Bellevue Hotel, which is one of the Government stations, we engaged a stolesjaerrie (pronounced stolecarré), and a first rate little pony; we arranged to keep this conveyance and the attendant for the few days we were in the Romsdal Valley. We preferred the stolecarré, as it was seated for two, hence the more sociable; but the most comfortable conveyance for the traveller in this country is the carriage—it is seated for one person only. The body of this vehicle is just like a round smoking-room chair, stuffed bottom and back, the passenger's legs stretching out to two small iron rod foot rests that are fixed from the tram to the bottom board, the usual space being left at the back of this bottom board for your luggage and your boy.

As a rule these conveyances are engaged from station to station, but we arranged to keep this one all the time we were in the district, rather than have six or seven changes in our journey through the valley.

The lad we got from the Bellevue to take charge of the pony and trap was a very intelligent young fellow and spoke excellent English—he had been over in this country for some time, hence his perfection in the language.

In this country it is usual for the traveller to drive himself, but if you so desire it you can have the boy to drive. When the boy is driving, should there happen to be any accident, or if anything was to go wrong with the horse or vehicle, you would not be held responsible for the same, but when you are driving yourself you become liable for damage if such should occur.

The ponies are sure-footed animals, and well-made little things they are, with full manes, long tails, curved necks, and full chested; the great majority of them are a sort of cream colour. They look made for their work, and to see their willing impatience one can't help observing that they had settled to do it. It is perfectly marvellous to see them rattling down steep, to the eye almost perpendicular, hill sides. Sure and steady without a trip; and where there has been deep ruts or holes in the roads, over and over again I have observed them just avert so much as kept the wheel from getting caught, and this without ever altering the pace. All over the country we were told that these ponies could be bought at from five to seven pounds apiece; and it seemed to me that if they were on this side they would have brought much more money.

On leaving our hotel we descended into the vale; the day was cloudy and the wind rather high for foliage pictures. The first exposure we made was on the Romsdalsfjord, one of the celebrated hills in the chain, it looked rugged and grand towering up some five thousand feet above the little bridge that crossed the river below.

This mountain is so precipitous and void of vegetation near the top that there is only hard and bare rock to be seen, and for a long time it was considered impossible to ascend to the summit of it, and many tourists had tried and failed; but in 1881 the feat was accomplished by a gentleman, but who, alas! when he got to the top found that some one had been there before him. A mound of stones was gathered together on the summit with an inscription showing that a mad shoemaker belonging to the valley had dared the ascent and succeeded in performing the task some fifty years before.

The next exposure we made was on the house of Mr. Wills of English tobacco fame. It had been an hotel previously, and it made a very pretty picture nestling amongst the trees on the slope of the hill. Even here, in this secluded spot amongst the wild hills, the march of scientific progress is observable, for we find the telegraph and the telephone playing their parts—the village, two miles distant, and this residence being united by wires. After taking this picture I started to turn the roller slide, when away went something inside snap, and the roll would turn no more—here was a fix! Jack proposed that we should go up to Mr. Wills's house, and see if we could get any place to turn into a dark room, so that we might have the slide put right if possible, but after talking the matter over we arranged to drive on to the first station, Horgheim, a distance of about eight miles.

As we drive on further down the valley, and at the other side of the rushing river, we come upon the mountain of the Goblins. On the top of this mountain, thousands of feet high, groups of rocks can be seen standing up on end and looking like crowds of human figures, and as we twist and twine along the beaten track we get tricked into the fancy that they are changing places and positions, and seem to be moving about in a demon dance.

MARK OUTE.

QUARTERLY REPORT OF PHOTOGRAPHIC PROGRESS.

[A Communication to the Birkenhead Photographic Association.]

I HAVE now the pleasure of presenting the second quarterly report of the progress of Photography.

The summer so far has been pre-eminently fine, and the opportunities for instantaneous exposures very great. Our worthy President, Mr. Paul Lange, who has just returned from a photographic tour in Norway (the land without a summer's night), tells us his 150 pictures were, of necessity, instantaneous exposures, and he fears that even with that precaution some will certainly be over exposed.

In my own experience in Barmouth and its neighbourhood, I found a similar condition of the actinic force, and took to an old single lens (by Ross), which I found to work admirably. The sensitive plate is now so quick that we may safely return to single lenses, only taking care that we avoid buildings at the extreme ends of the picture, such lenses being naturally liable to curved lines.

An important advance has just been made in the means of focussing cameras by Colonel C. O. Ellison, a member of the Liverpool Amateur Photographic Society, who has, I believe, taken the steps necessary to patent the invention, which consists of the attachment of a mirror or reflector to the outside of cameras having a back focussing plate, so as to show the intended view or subject the right way up, as in nature, instead of "upside down" as usually focussed; and the picture being seen from the top of the instrument instead of the back, the operator is enabled to stand in an easy graceful position while focussing instead of the stooping, cramped attitude, which we all know so well, and to dispense entirely with the hideous black sheet over head and shoulders; the light being kept from the reflector by a guard of black silk or any light non-porous material, or even a dark pocket handkerchief, arranged so as to receive the eyepiece or focussing glasses if preferred.

One great advantage of this patent is that it can be fixed to any kind of camera, and so simply, that it can be detached and refixed in half a minute; used or not at the operator's pleasure; and when not in use, or the photograph is being taken, is suspended under the camera ready for re-use, or lays flat against the back for travelling.

Another method of using the reflector is to attach it to the frame of the focussing screen or plate, and so fix the latter to the camera that both (screen and reflector) can be hung together as above, leaving no loose or unattached fittings to get broken or misplaced.

This arrangement also, by showing the picture from the top, allows of the use of very short camera legs, thereby securing freedom from vibration and reducing the weight to be carried by the amateur.

The adoption of this simple and improved method of focussing will prove highly acceptable to amateurs generally, and to the ladies it will be simply invaluable, saving hat, &c., from the horrors of the black cloth, and we may count upon a large addition of the fair sex to our ranks now that the grace so natural to them can be introduced even into the focussing part of our art.

I am glad to record that several members of our Society have taken up the re-enslaving of the stereoscopic department, and we hope to see a display of views at our monthly meetings, when attention should be given to the means of better and more conveniently displaying such pictures. Mr. Chadwick, of Manchester, is doing good work in this direction, and his introduction of Harnett's American dark slides is a great boon to amateurs.

I would suggest to camera makers the use of the well-known "ball-and-socket" joint between the camera and the legs, as a desirable improvement to ensure quick adjustment when about to expose. I would also suggest the introduction of a lock spring to the dark slides, so as to prevent the possibility of double exposure of the same plate.

I would draw attention to celluloid films, as possessing immense advantages in easy development and extreme portability. The best carrier is the question, and I see our old friend, W. B. Bolton, London, is

offering this to the public, the following paragraph appearing in last week's British Journal "Editorial."

[Here follows the notice of the film carriers of Mr. Bolton and Mr. Turnbull which appeared in last week's issue of this JOURNAL.—ED.]

THE EASTMAN TRANSPARENT FILM.—The substitution of paper for glass as a support to the sensitive film was a marked step in advance. Then came the American film for negatives, which, when completed, has many advantages over glass, particularly in lightness and portability. But this required the rather tedious process of transferring, and celluloid was hailed as a still greater improvement. It was transparent, light, and required no stripping. It, however, could not seem to be made thin enough, or in large enough sheets to be used on a roll holder. The Eastman Company now announce that it has overcome all difficulties, and can manufacture sheets of absolute uniformity of thickness fifty feet in length and only three-one-thousandths of an inch in thickness. This enables them to apply their new transparent film to the roll holder and the Kodak, and places in the hands of both professional and amateur photographers a vastly improved process. The specimen sheet which we have seen seems to be all that Mr. Eastman claims for it; certainly, the negative made on it, which he showed, is all that could be desired.—*Photographic Times*.

The above is certainly progressive, if not startling; the name of the Eastman Company is a pretty sure guarantee of its success, therefore, I say, look up your "roller slides," and prepare them for "celluloid film" adoption.

The realization of this will bring about a vast change in the photography of the future. There is no greater difficulty of the present day that meets the enterprising traveller to all parts of the world than the safe transit of sensitive glass plates over rough roads and ignorant handling. I hail this advent as the most successful article that has yet appeared to supersede glass as a support to the sensitive image; as a glass maker it it has served my time well, and in the language of my native poet, "Blessings on your frosty pow, John Anderson my Joe."

JAMES ALEX. FORREST.

KEIGHLEY PHOTOGRAPHIC EXHIBITION.

A Photographic Exhibition will be held in the Mechanics' Institute, Keighley, from January 6 to 18, 1890 (inclusive).

All pictures must be framed and mounted. No oval or Oxford frames will be admissible.

The Committee will undertake to unpack, repack, and deliver exhibits to the carriers for return at the close of the Exhibition, and will, by engaging professional assistance, use the greatest care, but at the same time the Committee will not hold themselves responsible for any accident which may occur.

Under no circumstances will the exhibitor's name and address be permitted on the front of the frame. The title only of the picture may appear on the front of the exhibit. The particulars of each picture must be written in ink on a special label (the required number will be forwarded by the Secretary on receipt of Form A), a separate label to be attached to each frame.

The Committee reserve the power to reject any exhibit which may be sent in. No picture or series of pictures having received a *First Prize* at any previous competition shall be eligible for competition in any class except Class XV.

In the Amateur Class the photographs must be entirely the work of the exhibitor—exposing, developing, printing, and toning. All enlargements and enlarged negatives must be accompanied by a print from the original negative, and in the case of retouching the same to be stated.

The entrance fee for one class only will be 1s.; and 6d. for each additional class. A charge of 2s. 6d. will be made to each exhibitor of apparatus and trade requisites.

Medals and certificates will be given. For further particulars apply to the Secretary, Mr. James Robson.

THE IPSWICH PHANTOM PHOTOGRAPH.

STRANGE COINCIDENCE.

FROM the *East Anglian Daily Times* we learn a strange sequel to the phantom photograph story we published a few weeks ago. We condense the following from its issue of Monday last:—

"Devout believers in psychical phenomena no doubt derived great encouragement from the so-called 'phantom photograph' which was taken on the River Gipping about two months ago. Their belief will probably be still further strengthened by the fact that on Saturday morning a woman's body was found in the Gipping at the exact spot where the photograph was taken. Some people will be inclined to look upon the photograph as a supernatural warning of the sad event which has just taken place, while other folks, and more wisely, will be inclined to treat it as merely a singular coincidence. However, the coincidence is undoubtedly a very strange one. The facts are briefly these. On Saturday morning Charles Hill was proceeding along the towing-path on the Gipping at the back of Mr. Peter Bruff's house, when he saw a woman's hat with a basket lying on the bank. Approaching nearer, he saw the

body of a woman floating face downwards in the water and near the other bank. Hill immediately went to find a policeman, and meeting Police-constable Folkard at the Barrack corner, the two returned together, first getting some drags. Police-constable Folkard threw a grapnel across the stream and pulled the body out, and it was then taken to the mortuary. The body was identified as that of Sarah Ann Porley, residing at 4, Clamps-buildings, Harland-street, Stoke. From the evidence of the deceased's neighbours, it appears that she kept house for an elderly man named Horace Watling. Deceased was in the habit of drinking very much, and on Friday night, while in a state of intoxication, she quarrelled with Watling. Finally the latter told her to leave the house or he would fetch a policeman, and she left in a rage about 11.30. The spot where the body was found is, as we have said above, the exact place shown in the 'phantom photograph,' and Sergeant Nunn, who was engaged to drag the river on that occasion, says there is not a yard's difference."

Our Editorial Table.

THE LONDON STEREOSCOPIC COMPANY'S NEW CATALOGUE OF APPARATUS.

A TRULY elegant little book of 192 pages, beautifully printed in two colours, and illustrated plentifully, not alone with woodcuts, but with several full-page pictures printed in various colours by the photo-mezzotype process in use at the Company's works. These in all cases are illustrative of the capabilities of the apparatus sold or made by them. Here we have a yacht under full sail, there a portrait of a child; an instantaneous view at the seaside during the bathing season; another view suggestive of a village in the Isle of Wight, roadside scenes, and so forth. It is a good idea, and one which ensures care being taken of the catalogue. The variety of apparatus catalogued is very great, and embraces everything known or required in photography. We notice just one mistake. In the price list of journals THE BRITISH JOURNAL OF PHOTOGRAPHY is catalogued as threepence, it should have been *twopence*. The work is beautifully printed on fine paper, price sixpence.

PATENTS COMPLETED.

IMPROVEMENTS IN THE CONSTRUCTION OF SUPPORTS FOR PHOTOGRAPHIC PICTURES, PLATES, OR FILMS WHILE UNDER MANIPULATION.

No. 10,865. WILLIAM HARDING WARNER, St. Augustine's Chambers, Unity-street, College Green, Bristol.—*June 15, 1889.*

THE object of my invention is to manufacture improved supports for sustaining one, two, or more photographic pictures, plates, or films when aluming, fixing, washing or otherwise manipulating the same. My invention consists of solid or hollow articles formed of vulcanite, india-rubber, glass, porcelain, stoneware, wood, or other suitable material.

These supports are used in pairs, each one being preferably in form of a right-angled triangle with the hypothenuse uppermost. When made of vulcanite or similarly firm material, two of the angles only are sufficient, viz., the hypothenuse and perpendicular formed of thin material, the sides and bottom being left open. In some cases the hypothenuse and two sides may be so formed, leaving the end and bottom open. The rests or supports are placed in position in one or more pairs with their slanting surfaces towards each other, the photographic pictures, plates, or films being supported upon the slanting surfaces. Plates of various sizes may thus be supported during manipulation, the larger plates above and the smaller below, and smaller supports and plates may be superposed over and upon the larger ones.

The plates are used in the washing tray or vessel with the film sides downwards or in other positions as required.

I do not confine myself to any particular angle in forming my improved supports, as any form which furnishes an angle of repose may be used.

What is claimed is:—The manufacture and use of angular supports, rests, or holders for photographic plates, films, or pictures in fixing, washing, aluming, or developing trays or vessels or analogous apparatus, substantially as described and illustrated.

IMPROVEMENTS IN HOLDERS, CLIPS, OR EASELS FOR PHOTOGRAPHS, MIRRORS, PHOTOGRAPH FRAMES, CARDS, AND OTHER ARTICLES.

No. 11,134. HARRY WHITFIELD, 68 Broad-street, Birmingham.—*June 15, 1889.*

My invention is primarily a metal holder or clip constructed to hold or clip a glass plate, behind which is held a photograph, picture, or card. It is also constructed to hold or clip a mirror, photograph, card, or other article. My holder, clip, or easel is composed of three arms of flat or round strips of metal or other suitable material, which are rivetted or in some other way loosely fastened together at the end of each arm. The other end of each arm is formed as a hook. These hooks are meant to clip or hold the article it is desired to hold.

To two of the three said arms of my clip is attached a spring which exerts an outward pressure.

Now when it is required to clip or hold a glass plate or other article by my invention, the one of the arms of my clip to which the spring is not attached is extended in one direction and the hook hooked over the edge, or otherwise; while the two arms to which the spring is attached are extended in an opposite direction, like the arms of a letter Y, and the spring being compressed, the two arms of my clip attached to it approaching one another lengthen the clip, and the hooks are hooked over the edge or otherwise of the article it is required to hold; the spring being released, the clip shortens, and thus holds or clips the article in the manner desired. Thus, when it is required to release the article held it is only necessary to compress the spring, and the two arms attached to it approaching one another, the clip lengthening looses the hooks from the article held.

Any kind of spring exerting an outward pressure will actuate my clip in the manner desired.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JULY 4.—Mr. W. E. Debenham in the chair.

A question being raised as to the making of a ten per cent. solution and the different weights and measures in use, Mr. A. HADDON said that a convenient way to make a ten per cent solution was to take an avoirdupois ounce of the required substance, = 437½ grains, and dissolve in water made up in quantity to 4375 minims.

Mr. A. PRINGLE mentioned a case in which the same subject was exposed twice upon the plate with the result of producing a second or duplicate image. The remarkable thing was that the two images were both distinct and did not appear to interfere with each other.

Mr. J. TRAILL TAYLOR said that Mr. A. L. Henderson, when in America, had found an image on the plate of a word that was printed on the shutter of the dark slide, and he argued from that that the slide itself was not perfectly opaque, but had let enough light through to print the word in question upon the plate. He (Mr. Taylor), however, had come to the conclusion that the image of the word was caused by an emanation of a phosphorescent character proceeding from the printed matter. It was well known, too, that some kinds of material gave off an emanation capable of fogging the plate; this was particularly found to be the case with the leather sometimes used as a hinge for the shutter of the dark slide.

Mr. HADDON observed that it was difficult to find a substance that was not to some extent phosphorescent.

On the subject of combination printing and printing from combined negatives, Mr. TAYLOR said that in the old collodion days he had seen excellent results obtained by taking two negatives and clearing off all that was not required in each by means of a chemical solvent; one film was then loosened from the glass support by acid and floated in the proper position on to the other negative. For printing from several negatives one after the other, there was the method of registering printing frames as used by Edwards and by Hemery.

NORTH LONDON PHOTOGRAPHIC SOCIETY.

JULY 2.—Mr. J. Traill Taylor (President) in the chair.

Mr. W. Few showed some plates marked by the packing, also a plate which had been exposed through the glass; it was sharp, but was marked by the emulsion which had been on the back.

Mr. G. J. Clarke showed a plate stained a deep yellow colour.

Mr. A. MACKIE said that the stain was caused by hyposulphite of silver, and the plate had not been fixed sufficiently, it being sweet to the taste.

The CHAIRMAN remarked, with reference to a Voigtländer's orthoscopic lens exhibited at the previous meeting, that the focus of these lenses was measured from a point outside the front lens, and not as in other lenses of single or double type.

Mr. Clarke showed some negatives on tannin plates, also an old wet collodion negative, and a copy of a print taken with a triplet lens.

Mr. J. DOUGLAS asked if there would be any objection to using acid in the alum bath for Ilford plates.

The CHAIRMAN replied that there would not; he had always used it.

Mr. W. BISHOP said that he used a little acetic acid in the alum bath before fixing.

Mr. MACKIE said that there was a theoretical objection to acetic acid, as it is a solvent of gelatine. He also recommended the use of two hypo baths for fixing plates, as it was far more important to fix them well than to wash them a great deal afterwards. Mr. Mackie drew attention to the American annual of the present year, in which a writer recommended the back glass of a portrait combination as an object glass for a telescope.

The CHAIRMAN said that this would be the worst lens possible for the purpose, as there was a great deal of negative aberration in such a lens, and one would not be able to see through the telescope as well as with the naked eye. The Chairman also stated that very fine photographic engravings could be obtained by coating a negative on the face with bichromate of potash and gelatine and exposing it to light through the glass; it should then be placed in water, which would raise it in relief, and when dry a cast could be taken from it either by fine plaster of Paris or by rendering the surface electrically conductive by bronze powder or silver and taking an electrolyte; the process gave extreme delicacy of results, and M. Placet, of France, had produced very charming engravings by means of it.

An excursion was arranged for July 16 to Loughdon.

The next meeting will be on July 16, and will be a general technical meeting.

EAST DULWICH AND PECKHAM PHOTOGRAPHIC SOCIETY.

JULY 5.—Mr. Dowling in the chair.

Mr. F. W. Edwards was unanimously elected President of the Society.

The following were elected members:—Messrs. Edwards, Fellows, and Homewood.

SHEFFIELD CAMERA CLUB.

THE first excursion of this Society was to Miller's Dale on Wednesday, June 28. Several friends (non-members) also availed themselves of the opportunity to visit this favourite locality. Although the Dale does not possess the grandeur of some others in Derbyshire, it presents most charming views equally well adapted for the camera as for the pencil. The course of the River Wye in the direction of Buxton is particularly interesting. The weather, being remarkably fine and still, was favourable to the pursuit of photography. A large number of successful views were taken, and a most enjoyable day was spent.

JULY 5.—Dr. Morton presided.

There was a good attendance, the subject of the evening being *A Lecture on Lantern Slide Making and Colouring*, by Mr. T. A. Manton, L.R.C.P. (Lond.), M.R.C.S. (Eng.). He recommended quarter-plate-size negatives and contact printing, using a suitable rapid rectilinear, and found most convenient an outfit consisting of a detective camera with time shutter. The lecturer gave a description of the different methods of development and toning, and afterwards demonstrated hand painting with water colour and oil. The latter method he adopts, and had found a satisfactory medium in a preparation known as Rowney's Oleo Excelsior. The brush charged with colour was dipped in the medium and diluted with a little turpentine applied to the slide, and then softened down with the finger. Clouds were picked out with clean cotton or linen rag. When the desired effect was produced the slide was subjected to gentle heat, which caused the paint to become hard and brilliant. The colours most in request were Prussian blue, burnt sienna, yellow, and red. The aniline dyes were not permanent, nor yet was rose madder a safe pigment. Great care was necessary to avoid dust of any kind, and the colours had to be artistically applied, and not too thick. The covering glass when stained a light brown or other tint gave a remarkable beauty to the slides. The process of painting a slide being completed, it was with others tested in the lantern.

In the discussion which followed the PRESIDENT said he had hitherto been rather sceptical as to the utility of colouring photographic lantern slides; perhaps it was due to the recollection of crudities of the past. The lecturer had, however, shown examples which proved the efficacy of careful tinting, and no doubt the practice would become more general.

Mr. H. RAWSON thought the toning by chemical means, as in the use of gold and platinum, &c., assisted very much the ordinary developers, and some subjects were not so suitable for colour as others.

A series of slides, various subjects and methods, were projected on the screen. The Secretary (Mr. Hardy) distributed notices of the forthcoming Exhibition of the Photographic Society of Great Britain, held in September.

LEEDS PHOTOGRAPHIC SOCIETY.

JUNE 26.—The President in the chair.

Mr. J. W. Ramsden was elected a member of the Society.

The question of the Society holding a Photographic Exhibition in connexion with the Municipal Fine Art Exhibition in the autumn was discussed, and it was decided that the Hon. Secretary should write the Fine Art Committee and ascertain what arrangements had been made.

The outdoor excursion to Fountains Abbey announced for July was arranged for the 17th, leaving Leeds at five minutes to eight a.m.

Mr. W. DENHAM then read a paper on *Various Methods of Photographic Printing*. [This will appear subsequently.]

MANCHESTER PHOTOGRAPHIC SOCIETY.

JUNE 21.—Mr. Abel Heywood, jun. (Vice-President), in the chair.

This was a special meeting called by the request of ten members, at which Mr. W. G. Coote (Treasurer) moved, "That any member joining the Society after the March meeting in any session be only liable to a subscription of half a guinea for the remainder of that session."

The motion was seconded by Mr. ALAN GARNETT, supported by the Chairman and others, and carried unanimously.

Question box:—"Is Darlot's 'Universal lens' now used? What was or is its combination?"

A member replied that it was a portrait lens, and so arranged in the mounting; that by removing one lens it could be used for landscape purposes.

"Has any member tried Blanchard's platinum process, and with what result?"

Mr. H. SMITH had tried it, and was understood to say he preferred the Platinotype Company's paper.

"Can any one recommend a reasonably cheap shutter for instantaneous exposures that will work without jarring?"

Various opinions were expressed, the majority were in favour of Kershaw's, price 18s. to 25s.

The HON. SECRETARY (Mr. W. I. Chadwick) said, as there was no subject before the meeting, he had arranged a small exhibition of detective or hand cameras. Having written all the makers of these instruments, he was glad to say several had arrived.

Mr. GARNETT then exhibited and described the Kodak from the Eastman Company, and also a very nice little apparatus from Messrs. Shew—the Eclipse camera—with dark slides and their patent changing back; this, Mr. Garnett said, was very simple and efficient when the instructions were complied with.

Mr. HEYWOOD followed by exhibiting and describing Messrs. Marion's various hand cameras.

Mr. JOHN SCHOFIELD took in hand the detective of Messrs. R. & J. Beck; and the HON. SECRETARY explained the camera sent down by Mr. Turnbull, of Edinburgh, the compactness of which was highly appreciated, as was also the film slides and carriers.

After various minor exhibits, the CHAIRMAN said he did not know whether members were in the habit of reading a somewhat new paper devoted to photography, which he had seen that week for the first time. In the number dated June 13 would be found an article signed "A. P." (which initials stand for Andrew Pringle), on the subject of *Stereoscopic Photography*, which seemed to have been called forth by an earlier article in THE BRITISH JOURNAL OF PHOTOGRAPHY, written by Mr. W. I. Chadwick. Mr. P. began by announcing that he was about to write a strong communication, at least one which should not be charged with being "weak and misleading," but he had fallen into the error of supposing bluster, denunciation, and abuse to be strength; there was no exhibition of strength in the thing said, and none of the power shown which knowledge of a subject can alone give. The article professed to be on the stereoscope, but it was almost as much on binocular vision; and Mr. P. seemed to complain that the Almighty had given men two eyes when (as we may presume he argues) one would have done better. "The true effect," he says, "of atmosphere or distance is to be attained not by more or less looking round corners which almost describes binocular vision, but by—" something else, no matter what. Instead of a stereoscope for producing the illusion of solidity, let a person look at a photograph or a painting through a pinhole and he will have "quite as much [of solidity] as is good for him." Mr. Pringle objected that "a short lane of trees is often by a stereoscope made to look miles long (!), and this illusion can be produced at will if the worker has any intent to beguile." Therefore, argues this guileless writer, the stereoscope ought to be discontinued and classed among other toys like "Rupert's drops, Pharaoh's serpents, suckers," &c., which Mr. P., it is to be hoped, can write more intelligently of than of a stereoscope. Just as reasonably might he condemn the whole art of photography because by photography it is quite possible to make a gooseberry bush look as high as a house. A stereoscope "might interest a scientific observer for a few times," and "might astonish a child or a savage for a few times," and so on. This kind of twaddle is put forth as an example of strong writing! But the climax of absurdity is reached when Mr. P. declares that he has not looked into a stereoscope for many years. Who will doubt it? Mr. Heywood continued that there was more of such writing in the article, but the specimens given were probably sufficient. He concluded by showing a number of stereoscopic slides taken on a recent excursion of the Society to Gawsorth, in order that members might see some charming illustrations of natural scenery shown with natural effect by the instrument "A. P." had so shamefully libelled.

The meeting was brought to a close by an inspection of works by various members taken on the recent holiday rambles of the Society, amongst which were some beautiful stereoscopic slides by the Chairman, taken on Carbutt's films. Several other members exhibited stereoscopic slides. It was said that over twenty-five members were now working stereoscopic photography.

DARLINGTON PHOTOGRAPHIC SOCIETY.

JULY 8.—Mr. G. Newby Watson presided.

Mr. H. W. HOLLIS opened a discussion on *The Photography of Interiors*, which was illustrated by several photographs, some of which showed that the great difficulty to be overcome in this branch of photography was halation.

Several members took part in the discussion, and Mr. G. NEWBY WATSON stated that negatives taken by him on Eastman's films showed no trace of halation.

The subject for discussion at the next meeting will be *Vignettes and Vignetting*.

PACIFIC COAST AMATEUR PHOTOGRAPHIC ASSOCIATION.

JUNE 6.—President Runyon in the chair.

A resolution was passed admitting ten members, at fifty dollars each, to life membership, the proceeds to be used as a room fund.

In response to the prize competition for studies suggested by Longfellow's *Building of the Ship*, only two pictures were received. It is to be regretted that they were withdrawn on account of non-competition, for they were both excellent. Had there been lively competition it had been the intention of the Association to publish the study considered by the Judges as the best, and to furnish each member with a copy made by reproduction; the original was to be framed and hung upon the walls of the rooms of the Association. This suggests that did each association in this country give a subject for com-

petition among its own members, publish the photograph of the successful competitor, and exchange with the different societies, artistic effort would be stimulated, each member would try to rival his fellow, and each society would endeavour to reproduce that picture which should be finally decided to be the most successful of all presented.

A Committee was appointed to revise the constitution and bye-laws of the Association. This important work is necessary because of the rapidly increasing membership. At present none but amateurs can become members, and there are certain restrictions against any member selling his work. In the revision it will probably be decided whether it is advisable to admit professional photographers, and also whether there is a sufficient number of lady amateurs in San Francisco to warrant the Association in making special provisions and arrangements for their membership.

CINCINNATI CAMERA CLUB.

The first meeting in June was well attended, Mr. Bullock occupying the chair.

It was suggested that the Club take a number of "outings" during the summer months, to be conducted by volunteer members. This met with great favour, and immediately the excursions were provided for.

Mr. Johnson showed a circular level, which was of great interest, and was pronounced of advantage to the worker both for its accuracy and convenience.

Mr. BARTON read a paper on *Composition*, with charcoal illustrations.

On June 17 the second meeting was called to order with Vice-President Fisher in the chair.

A question of having one meeting instead of two for the months of July and August was brought up, and decided that, as the times for meetings were fixed by a constitutional provision, no action should be taken.

Prints from negatives made at the "outing" were shown, and it is remarkable that, bad as the day was, many choice pictures were made.

Mr. HOWARD KINGSBURY, of the Philadelphia Society, entertained the Club with a paper on *Luray Cave and the Theory of its Formation*, with lantern illustrations. Mr. Kingsbury showed himself to be thoroughly competent to handle the subject, both descriptively and illustratively. All the pictures were made by the use of the electric light, some requiring twelve hours' exposure, giving some idea of the time and patience required to secure them.

Correspondence.

✎ Correspondents should never write on both sides of the paper.

JULY MEETING OF THE PHOTOGRAPHIC SOCIETY OF FRANCE.—DEATH OF M. FERRIER.—DONATION OF 5000 FRANCS TO THE SOCIETY.—HYDROQUINONE A DANGEROUS PRODUCT.—PUBLICATION BY MM. GAUTHIER-VILLARS OF AN "ENCYCLOPEDIA OF PHOTOGRAPHY."—INSTANTANEOUS 14 × 17 INCH NEGATIVES.—PRESENTATION BY MM. ORELL FÜSSLI OF MECHANICALLY COLOURED PHOTOGRAPHIC PICTURES.—AN IMMENSE CAMERA.—A NEW AND INTERESTING CARBON PROCESS.—PHOTO-MICROGRAPHY.—A BANQUET.—PHOTOGRAPHIC JURY AT WORK.—PERMISSION TO TAKE VIEWS IN THE EXHIBITION.—THE CONGRESS.

THE Photographic Society of France held their monthly meeting on Friday evening last, the 5th instant, M. Davanne in the chair.

This gentleman informed the members of the death of M. Ferrier, one of the founders of our Society, and whose reputation for his stereoscopic slides was European.

The Secretary was requested to write letters of condolence and express the unanimous regret of all the members for their bereavement.

The Chairman then read a letter in which M. Ferrier, the son of the departed, had offered a donation of 5000 francs to the Society in memory of his father, the interest of which sum should be given as a prize for any photographic competition which the Society may organize.

The Secretary read a letter from a member warning operators on the poisonous effects of hydroquinone. He says that this product produces the same symptoms as bichromate of potash, and has a most injurious effect upon the hands.

A word of warning is here given to the fraternity. It would be well if other manipulators came forward and stated their experiences on this point. As to myself, I spent six months travelling, during which time I developed about 900 whole plates under the most unfavourable circumstances with the chemical in question. I sometimes observed its caustic action at the end of the fingers and by a slight inflammation under the finger nails, but nothing serious enough to condemn its employment.

MM. Gauthier-Villars, the great publishers of photographic literature, made a donation of the first fascicle of the *Encyclopedia of Photography*, by M. Charles Fabre, D. Sc. This is to be a monthly publication. The first number treats of light and photographic optics, with an introduction on the history of photography. The author has spared no pains to place the subjects in a clear and concise manner before the reader. The editor has gone to great expense to make it a specimen of the printer's art. This publication must find a place in the archives of every devotee of photography. A vote of thanks to MM. Gauthier-Villars and Fabre was passed.

M. Grascin, of Boulogne, presented some very fine instantaneous pictures of vessels going out of harbour, as well as the negatives from which these prints were obtained. The President observed that he was pleased to see that amateurs were now about to change the current of fashion by making large negatives instead of the too many small ones

which were so abundant. M. Grascin deserved praise in that his negatives were 14 × 17 inches—making pictures in themselves.

M. Grascin, in answer to questions, said he adopted hydroquinone as a developer; he did not seek a rapid formation of the image, and found that a slow developer gave the best results. The bottles containing the developer should always remain full and well corked. In order to attain the former desideratum, he lets fall into the bottle pieces of glass (marbles or beads), until the liquid touches the cork; the developer by so doing preserves its qualities for a very long time. Some surprise was expressed to see such large negatives taken so rapidly, and at the same time so sharply defined. I employ, said he, a Hermagis lens, having a focus of eighty centimetres and a diaphragm of three and a half centimetres.

Prof. Stebbing, in the name of MM. Orell Füssli, of Zurich, presented a large mechanically coloured photographic picture, stating that during his visit to Zurich he had the good fortune to visit the establishment of those gentlemen, and to see how they had brought the old bitumen process to perfection in that they are able to reproduce nature with its harmonious tones, and paintings with all their colours.

A large field is open for Swiss enterprise, which will not only bring honour to the country, but wealth to the workmen as well as to the masters. The proof presented represents one of the Alpine ice fields, with snow-capped mountains, and in the foreground (happy contrast!) a sunny and cultivated district. The colours are happily blended together and form a harmonious whole—a Swiss scene in all its natural beauties.

This house has already sent into the market a collection of coloured photographs, entitled, *Winter Scenes in Switzerland*. These have met with general satisfaction in the Paris Exhibition, where they can be seen in the Swiss section.

M. Bréhon presented the drawings of a large camera made for the Crenot establishment by MM. Gilles Brothers; this immense camera is now exposed at the Champ de Mars.

M. Victor Artigue presented his new carbon paper, and developed an image on the same before the Society. As his method is new it requires some explanation. He coats a paper with some pigment; not a tenth of the colour is required as in the old process. When about to use it a two per cent. solution is daubed (permit me this expression) over the back with a brush or a sponge; it is then dried and exposed in the printing frame. After insolation the paper is attached to a narrow flat piece of wood by means of two pegs; it now floats or hangs like a flag.

M. Artigue now performed a novel mode of developing the image. In a large earthenware basin a certain quantity of warm water was poured. Into this water was thrown a quantity of fine sawdust well stirred. The operator then took hold of the piece of wood to which was attached the undeveloped carbon print, the latter hanging down perpendicularly. He took a certain quantity of the sawdust and water in an old coffee-pot and deliberately poured the contents along the top edge of the paper. This manoeuvre was often repeated, and after a certain time the image began to appear. It appears that the sawdust dribbling down the surface of the print carries with it the unmodified gelatine, and the colour with which it had been impregnated, leaving naturally the insoluble substance with the colour to form the image in all its details, half tones, &c. By this new system no transfer is required, as the image is washed on the front and not from the back, as in the ordinary way.

The finished image has quite another aspect from that of a carbon proof. It gives a dull surface, very artistic; the blacks are very dense, and the whites very pure indeed. A number of specimens which were passed round won the applause of the members. This new idea will probably bring the carbon process into favour; if so, we may legitimately expect to hear and see very much of it ere long.

M. Duchene, who has occupied himself very much with photo-micrography, exhibited the results of his labours. An enlargement of the *Pleurisigma Formosum* was very much admired.

Many objects had attained a diameter of 7-500.

M. Mariller presented a camera all in brass; with the exception of the bellows, none of the modern appliances of swing back and front being adapted I found it wanting.

The Secretary informed the members that everything was being prepared to do honour to the fiftieth anniversary of the introduction of photography. A banquet would be prepared, followed by a brilliant *soirée*, instrumental and vocal music, &c. The price to members and their friends would be thirty francs. He (the Secretary) hoped that foreign photographers and members of photographic societies and clubs present at Paris for the Exhibition would make it international by taking part in the festivities. Tickets can be had on application to any member of the Photographic Society of France.

The Jury of Class XII. examined last week very carefully the exhibits of the British section. Although very few, quality was not wanting. The exhibits of Mr. Thomson, Van der Weyde, and Walery, were particularly favoured, not to say that others were neglected, far from it. The photographic Jury is renowned as being one of the most conscientious in their work.

Great dissatisfaction is felt as to the arbitrary manner in which the permissions to photograph in the Exhibition are dealt out. A sum of 300 francs must be paid for each camera employed: that sum covers the duration of the Exhibition, and the happy payer of 12l. can work from morning until the close of the gates at eleven at night, if he be inclined to do so. Another system is employed: By the payment of twenty francs

per camera one can take views from eight to twelve, or from ten to two o'clock. Any one infringing these rules by working in other hours, or surreptitiously using a camera without prepayment, entails the loss of the instruments employed, and can be fined 16*l*. To pay twenty francs for four hours' work appears a large sum, especially when the weather turns out unfavourable. This is not all, twenty-five cents stamp duty, the entrance fee and loss of time, make it a heavy tax; not only this, but many parts of the Exhibition cannot be photographed. The sole right to take views from the Eiffel tower has been sold by that enterprising gentleman to a photographer. The Rue de Caire, says the builder, is private property, and I have sold the right to take views to "Mons. X." In fact, obstruction is so persistent—said a poor photographer—that during the four hours he got only two exposures, having been interrupted in his work by every policeman who passed, the latter requesting to see and read most attentively the permission. This aged photographer had his camera fixed on the top of a high double ladder, and I can judge of his dismay in being ordered down every now and then to exhibit his right to be there, &c. In the beginning the Directors of the Exhibition made still heavier terms, and wanted to make an exorbitant revenue from these photographic permissions, but, thanks to the energy of the "Chambre Syndicale de la Photographie," the price, although still dear, is not so heavy as it might have been.

Several persons (foreigners) have been arrested for using detective cameras; their pleading ignorance is of no avail. Two English ladies were pounced upon the other day, and I had great difficulty in saving their apparatus.

The International Photographic Congress have commenced work. The nomination of the Committee may be criticised, they being all French, which is not very international; but a compensation is offered, or a bone thrown to foreigners in this wise: they are admitted to assist at the meetings by the small payment of ten francs and their entrance fee when the sittings take place within the precincts of the Exhibition, when the meetings are held in the hall of "La Société Française de Photographie" no payment is required.

The Committee hope that a great number of foreign photographers, amateurs, &c., in Paris for the Exhibition, will pay their ten francs and assist in the discussions.

The Jury will soon have finished in the photographic section of the Exhibition; an account can then be given of work exhibited.

196, Rue Legendre, Paris.

PROF. E. STEBBING.

FILM CARRIERS.

To the Editor.

SIR,—I have to thank you for your notice of my film carrier in last number of the *JOURNAL*. But as at the same time you notice a film carrier, and give Mr. W. B. Bolton the credit of inventing it, I would like to lay one or two facts before you.

A good few months since I turned my attention again to film carriers and slides (I had when the Eastman carriers came first in the market done this), and the double carrier you credit Mr. Bolton with was one of the first I had made. I, however, did not like it, as it is too wobbly when of large size, unless made very heavy, and the single carriers I send out suit better. If, however, there is an advantage in carrying a lot of films in an ordinary slide, I have provided for it by making a single carrier that will carry half a dozen or a dozen films if required. The carrier I enclose will show this, the front film being best separated from the others by a film stained with chrysoidine or other coloured dye. The front film being exposed is moved to the back, and the stained film is also moved one film back, and so on till the whole are exposed.

I now send you one of my film slides, from which you will see that the double carrier which you credit to Mr. Bolton is carried out, only in a better way, as in a slide it is perfectly strong. I also enclose you a piece of folded brass to show how the slide is kept light tight when the shutter is drawn. The rubber cloth is pressed up from below by small india-rubber tubing and is thus kept perfectly light tight.

On the 10th of May I applied for a patent for the slides and carrier, and about a fortnight after that Mr. Bolton applied for a patent for the same thing. My patent covers all that he has asked a patent for, and I need hardly tell you that the party who takes out a patent first is the patentee, and that any subsequent applications for patents to other parties are of no use. Neither the single nor double carriers are new, but the application to carry films is, and if there is any credit in the matter at all it certainly is due to me, as both the film slides and carriers were in the hands of parties in the trade before ever Mr. Bolton applied for his patent. There is, also, at least another camera in the market which is clearly an infringement on mine, and I am at present under advice as to whether action will be taken to stop the sale of them.—I am, yours, &c.,
6, Rose-street, Edinburgh. J. M. TURNBULL.

[Mr. Turnbull's dark slide is certainly neat and most effective. Its thickness is only five-sixteenths of an inch, or (must we adopt the metric system?) nine millimetres. There is an opaque septum in the middle, and there are the necessary appliances for inserting and keeping flat the celluloid or other film. The shutters of Mr. Turnbull's dark slide draw out entirely, it being impossible from the nature of its construction that any light can obtain access to the

plate. With respect to the separate film holders we may state that there is this distinction between those of Mr. Bolton and Mr. Turnbull, which we saw and reported upon, that Mr. Bolton's has ledges on both sides for holding the film, Mr. Turnbull's partaking of the character of the holder originally introduced by Mr. Merritt, in which one holder serves as a backing for one film. On this subject of film holders we have more to say in an article on another page.—Ed.]

MOUNTANTS.

To the Editor.

SIR,—I should be much obliged if you would let me know of a clean and easily worked mountant. When asked, almost everybody answers, "Oh, I use starch," but I have never got it satisfactory yet, owing no doubt to the way of making it. Though I find toning, fixing, &c., of silver prints (albumenised) easy enough, yet the mounting always "stumps" me.—I am, yours, &c.,
16, Inverleith-place, Edinburgh, July 9, 1889. R. G. MITCHELL INNES.

[We went over the Stereoscopic Company's mounting rooms a few days ago, and greatly admired the facility with which their mounting was effected. They used as a mountant a solution of gelatine, which must have been carefully filtered, as there was not a speck to be seen in it.—Ed.]

DARK LIGHTNING FLASHES.

To the Editor.

SIR,—There has been a great deal said lately about dark flashes of lightning appearing on photographic plates, and, to say nothing of calling them by such an absurd name, they seem to be a kind of puzzle. I wonder if I have found a possible solution in ascribing them to a species of solarisation; and that instead of being dark, they are so intensely bright as to cause the plate at that part to be greatly over exposed, and so produce the reversed action sometimes found in over-exposed plates. I have not yet seen a photograph of a dark flash, so I may be drawing a conclusion altogether at variance with the effect produced.—I am, yours, &c.,
413, East India-road, July 6, 1889. GEO. H. SLIGHT.

Exchange Column.

* * No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Wanted, portable whole or half-plate camera and lens in exchange for tricycle.—Address, E. F. USHERWOOD, Dorking.

Marion's hot rolling press and burnisher (cabinet) in exchange for Show's or other good half-plate detective camera.—Address, P. PILCHER, 15, Castle-street, Dover.

Wanted to sell or exchange, an excellent stereoscopic or copying Dallmeyer lens (good as new) for an instantaneous shutter that registers time exposures, Newman's preferred.—Address, MISS MABEL NEWCOMBE, Dorman, near East Grinstead.

Studio chair, two backs, whole-plate burnisher, 12x10 rapid rectilinear, Kershaw shutter, pneumatic discharge; wanted, Ross' rapid symmetrical or Beck's rapid autograph, sixteen-inch equivalent focus.—Address, W. H. SLOWICK, Photographer, Seelberg, Yorkshire.

Wanted, in exchange for twelve volumes of the *English Mechanic*, down to present date, any useful studio accessory, such as curtain, tablecloth, background, pedestal, posing chair, or telescope that will show astronomical objects fairly, or glazier's diamond in good order.—Address, HORTON, Photographer, Caroline-street, Cardiff.

Answers to Correspondents.

* * Communications relating to Advertisements and general business affairs must be addressed to "H. GARNWOOD & Co.," 2, York-street, Covent Garden, London, W.C.

All matters for the text portion of this *JOURNAL*, including queries for "Answers" and "Exchanges," must be addressed to "THE EDITOR," 2, York-street, Covent Garden, London, W.C. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.

PHOTOGRAPHS REGISTERED:—

S. Lees, Douglas, Isle of Man.—Two photographs of the *Letins troupe*.

DRAUGHTSMAN.—Try silk mackintosh, which is thin and impervious to light.

W. S.—You have proceeded rightly enough, but you have not sufficiently washed the plates between the different operations.

KENT.—After reducing negatives with perchloride of iron they should be fixed again to remove the chloride of silver produced. Surely no one who understood the subject told you differently.

G. CORRY. The plates have evidently been "light-struck," that is, they have been exposed to light at some time or other; probably in the drying or packing. Do not waste further time over them.

MORRANT.—We never publish the addresses of our correspondents in this column. If, however, you send a letter here addressed "Care of the Editor," we shall be happy to forward it on to the gentleman.

S. A. STONE.—The exaggerated perspective in the picture sent is due to the use of a lens of too short focus, hence it includes a wider angle than is pleasing. Obtain a lens of at least a third longer focus than the one you are now employing.

W. INALL.—Before attempting to strip the negative by Plener's method with hydrofluoric acid the varnish must be first removed. Soaking the negative for a time in methylated spirit will accomplish this, particularly if assisted by gently rubbing the surface with a pledget of cotton wool.

C. B. W.—Good portraits can certainly be taken in a studio lighted from the south; but as you say you are just beginning portraiture and can put your studio up in any aspect, we should advise you to avoid the south, as it is always more troublesome, even to skilled hands, to work than any other.

L. M. inquires: "Can you or any of your readers tell me if I can buy dry plates $4\frac{1}{2} \times 3\frac{1}{2}$ in Switzerland? if so, where and what make? Lausanne would do for the former and Lumiere for the latter. Also if half-plate (English size) can be got. I think of going to the Rhone Valley. Any hints will much oblige.

G. BLANKLY.—Reduce the proportion of the bichromate of potash from five to three or three and a half per cent. during the summer months. Take care that the temperature of the solution does not exceed 60° when the tissue is immersed. Do not depend upon the time of the immersion, but judge by the laccidity of the tissue.

A. J. B. inquires if we can tell him of a large provincial town where the club system has not yet been introduced, as he would like to commence business there with a good-class picture.—We think it would be difficult to find a large town or even village in England where the club system in portraits is not already introduced. We certainly know of none.

A. Z.—It is impossible for us to give you the desired information as to whether the exigencies of the Copyright Act have been strictly complied with in any one particular portrait which is published. We cannot tell whether the work was actually done by the man in whose name it is registered or not. If you pirate the work you will have to take the risk for so doing.

A. D. R.—If, as you state, the lens was purchased from a first-class maker, he will, or ought, for the sake of his own reputation, to take it back upon your showing that it is defective in the sense of not covering in a satisfactory manner the plate it purports to cover. Take a negative by it with its full aperture, and submit it to the maker. Perhaps you are expecting more than such a lens will reasonably perform. We know of no place where it can be officially tested and reported upon.

C. J. FARLIE writes: "Can you advise me the cause of my toning bath going a brownish tint? The bath is the borax one. I find it takes a very long time to get through a batch of prints. It has only behaved so lately."—Probably the materials used in compounding the bath contain some foreign matter which causes a precipitation of the gold—impure water or a bad sample of borax, for example. Some samples of ready-sensitized paper are very prone to bring about a spontaneous reduction of the gold after the bath has been once used. When a toning bath becomes discoloured it is a sure sign that the gold is being precipitated.

M. says: "May I ask your assistance in putting me right? I made some collodion (five hundred ounces) for enamelling as follows:—Alcohol, four hundred parts; ether, six hundred parts; gun cotton, eight parts; castor oil, about half an ounce. It flows on the glass very nicely, but there is a great difficulty in getting the prints off again; about half stick hard and refuse to leave unless they are soaked off. The collodion on drying, instead of chipping off in a fine film, appears to me to dry powdery or leathery, as, if you scrape it, it forms a small lump instead of film, also in drying it dries opalescent and very dead-looking. May I ask you if you can tell me what is wrong, and how I can put it in working order?"—Our correspondent's trouble appears to arise from two sources, both separate and distinct. The sticking to the glass is no doubt due to the plates not being perfectly waxed or French chalked, and not to the collodion itself. The opalescence of the collodion is a different matter, and is a defect in it. This may arise either from the use of an unsuitable pyroxyline, or, what is more probable, employing solvents containing too much water. We fear there is no means of improving the collodion now made.

G. B. (Leicester) says: "Will you kindly tell me, in enlarging from negatives on bromide paper (by daylight, through aperture in wall and a reflector outside), at what distances I must place the centre of the lens (stop plate) from the negative and also from the paper to enlarge four times, i.e., from 11×9 to 22×18 , 10×8 to 20×16 , and $8\frac{1}{2} \times 6\frac{1}{2}$ to 16×12 ? The lenses I can use are Ross' rapid symmetrical, sixteen-inch focus; Ross' portable symmetrical, nine-inch focus; and Ross' doublet, twelve-inch focus. Which lens will do the work best as to sharp marginal definition? My reason for asking instead of trying for myself is that I have (at present) neither convenience to do so nor any experience, and I am just about altering a room for the purpose, and it may save me some expense to be on the right track at first instead of having to alter again. I expect also to be able to use the same arrangement for reduction from negatives to lantern slides by wet collodion in the camera. Is 'four times' too great a strain on the definition of the negatives to expect a good result? Mine are always as sharp and clean as they can well be got."—Here our correspondent only wishes to enlarge two diameters, and the best out of the three lenses to use is the rapid symmetrical. A table of enlargements will be found in the ALMANAC for the current year, on page 610. From this it will be seen that to enlarge two diameters with the sixteen-inch focus lens the paper must be forty-eight inches and the negative twenty-four inches from the optical centre of the lens.

REV. R. C. McLEOD inquires: "Am I justified in copying photographs which I have bought for the purpose of making lantern slides, and using these slides in lectures for which there is no payment at the doors, but after which there is a collection for charitable purposes? I presume that if there is payment at the doors I should certainly not be able to use slides so copied, and if there is no collection after I as certainly infringe no copyright. If I am wrong in these ideas kindly set me right."—If the photographs are copyright an infringement of the law takes place by copying them for any purpose whatever. The better way will be to write to the photographer for permission to make lantern copies for the special purpose mentioned.

J. H. BROWNING (Victoria, Australia) writes: "I wish to ask a favour of you. Can you tell me how to get any warmer tone on a transparency by the wet collodion and iron development? I make lantern slides by the wet collodion process and develop with iron. I have tried most other methods, but I like the wet collodion best. I have tried tannin plates, and these sometimes (only) give a warm brown tone; this is the sort of tone I should like to get on the wet plate if it is possible. I have seen some slides, said to have been on wet collodion plates, which had the tone I am trying for. I have tried a good many methods but cannot get anything much different from the slaty tones I do get, and I find out here no one seems to be able to get anything much different. The sulphide of potash does not yield the result in my hands it is said to give. Gold I have tried, and many others, but with indifferent success. I can, of course, get black tones by the silver, but this looks heavy and harsh in the lantern. Now, sir, can you help me, or is it a matter of impossibility? I get sometimes by the iron developer a red image, but this is uncertain and not under my control; my opinion is it is probably due to atmospheric conditions. I may say I am well up in making these slides by the wet method, and with the exception of the tone they leave nothing to be desired. The dry plates I have tried, but they do not give the result the wet plates do. The chloride plates also I do not like. As I have said, I have been shown wet plates with the tone I should like (brown or warm purple), but I have never succeeded in getting it. The tannin plates yield sometimes the tone I am striving for."—In reply: Warm brown tones are somewhat difficult to obtain with wet collodion and iron development. Something depends upon the exposure—the fuller this is the warmer will be the tone of the resulting picture. Brown tones may be obtained in the following manner: Give a full exposure, and develop a thin image with the iron; fix and wash thoroughly. Bleach with bichloride of mercury and then treat either with sulphide of potassium or ammonia. If our correspondent could always produce, as he sometimes does, a red image in the first instance, this could then be toned with gold, either to brown or purple, without difficulty. Wet collodion with a full exposure, and pyrogallic acid development, only, yields a brown tone which can subsequently be toned with gold. But with this development the exposure must be very prolonged.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Thursday, July 18, 1889.—Subject, *The Right to the Negative*.

PHOTOGRAPHIC CLUB.—At the next meeting of this Club, July 17, 1889, the subject for discussion will be on *Making Lantern Slides from Engravings and other Pictures*. Saturday outing at Chorleywood. Train from Baker-street at twenty-nine minutes past two.

PROCESS WORK IN THE FRENCH EXHIBITION.—The chief evidence of recent progress visible in the French exhibits is in the matter of process engraving and printing. The number of different methods of which French publishers can avail themselves appears to us considerably larger than those with which our own publishers are familiar, and the French printers are evidently paying special attention to modes of working adapted to the various engraving processes. The applications of photographic engraving for lithographic and typographic printing, and also for the same work in colours, are exhibited in many different specimens. Colour printing in relief is specially exhibited by Draeger & Lesieur, Quantin, Charles Unsinger, and A. Lahure. Colour printing from plates by Bonssod Valadon et Cie. and Charles Chardon. A special process of printing photogravures in colours is shown by M. Mouillot, Director of the Publications Périodiques. Process work from zincs in black and colours is done with special excellence by Georges J. Petit Michelet, Rongeron, Guillaumé, and Gillot; photo-lithography by Berthaud and Aron; and photogravure by Dugardin and Bonssod Valadon et Cie. Some of these printers do not exhibit, although many specimens of their work are to be seen in different cases. In the French section there are altogether one hundred and eighty-seven exhibits, those of the great houses, such as Hachette et Cie., Plon, Nourrit et Cie., Alfred Mame et Fils, the Maison Quantin, and Firmin Didot et Cie., filling the space of a moderate-sized shop, handsomely, not to say luxuriantly, fitted up. Hachette, Mame, and Didot are ineligible, members of those firms being jurors, and the gold medal will therefore probably fall either to Plon or Quantin.

No. 1524. VOL. XXXVI.—JULY 19, 1889.

CELLULOID.

Now that there seems to be every probability of glass being, at least partially, superseded by celluloid in negative work, especially out of doors, we may expect soon to find a new subject for discussion in the question as to whether the substance referred to is altogether free from faults in its new application. It may be said, indeed, that the question has already been raised.

It is no new thing in photography to find that when a new product or material is brought into use it at first enjoys nothing but praise from those who first experience the novelty of its advantages without recognising its defects. Later on comes a period when it suffers as much condemnation from those who, its novelty having worn off, are beginning to find out its defects, or rather what, from imperfect knowledge of its proper use or treatment, are supposed to be defects. Then, finally, the road branches off in two directions—either the thing is utterly condemned, or if really good, its peculiarities having been studied, it takes a firm footing as an improvement on what has gone before.

We have almost forgotten the many *pros* and *cons* urged in connexion with collodion after its introduction nearly thirty years ago into the photographic laboratory; but every one must remember the paeans that were sung in favour of gelatine when that first showed its capability of replacing collodion Pyroxyline—so said the enthusiast of that day—was a treacherous, uncertain, and unstable substance at the best of times, but gelatine—well, gelatine was gelatine all the world over, and could be obtained as a reliable and uniform product in any village shop.

We often wonder whether the preachers of that doctrine ever felt "small" in the after years of, say, from eight to ten years ago, when "frilling," "blistering," "pits," "green fog," red, yellow, and every other kind of fog and stain nearly drove plate makers and plate users to their wits' ends. When plate factories had to be "run" in the night hours and the days devoted to rest, when a spell of hot weather well-nigh put a stop to work altogether in studio or dark room, except at a ruinous expenditure in ice. No! gelatine did not, for photographic purposes at least, bear out the simple character at first claimed for it, and it is certainly not too much to say that photography brought about such a re-study of gelatine as to cause an entire revolution in its manufacture.

It is scarcely possible or likely that a purely artificial product like celluloid will be found in use to present the variations and uncertainties met with in the case of gelatine, but it is quite certain that before it is finally given a fixed place in photography it will meet many opponents and many adverse critics, both interested and otherwise. It will take time, of course, to fairly

decide upon many points in its character, and to establish or demolish its claim as a perfect substitute for glass. So far we can say no more than that it is, apparently, as near perfection in that direction as we can hope to approach, but it remains to be seen whether it does or does not develop at present unrecognised features which may materially detract from its advantages.

For instance, some few months after the first introduction of the Carbutt films into this country, in consequence of the occurrence of several cases of "spotty" negatives, the question was raised as to the possibility of chemical action taking place between the sensitive film and its support to bring about this result. At first sight this does not seem at all probable, and yet the argument was brought forward that in the case of *collodion* dry plates a deterioration occurred with time that was generally set down, if not absolutely traced, to partial decomposition of the collodion film itself and the consequent reactions upon the sensitive silver salt. And after all, in what does celluloid materially differ from a dry collodion film?

It certainly differs in one respect, and here again the promoters of the theory of chemical action find a peg on which to hang an argument. Without going into the precise modes of preparation, which may vary, it may be said that camphor forms a considerable ingredient in its composition, as is plainly evident to the sense of smell, especially when the celluloid is scraped, cut, or heated. "May not camphor, in time, exert an injurious action on the over-lying layer of gelatino-bromide?" So, at least, ask the dubious ones, and we can only reply that it remains for time to tell, though certainly the suggestion does not seem to be one to cause much uneasiness, at least as a cause of spots. If the fault complained of were general fog there would be more plausibility in the suspicion, since the uniform diffusion of the indicted substance throughout the film would favour general rather than selective or local action in case any injurious property were possessed by it.

Glass has, at least, one incontestable quality, namely, that it is about as chemically inert as it lies in human power to make anything. In a great measure celluloid possesses the same characteristic, but it is clearly open to the charge of liability to internal decomposition, resulting not only in the giving off of nitrous products, but also of the volatile camphor which forms a part of it.

If it should be proved that these doubts are well founded, the question suggests itself as to whether the beautiful substance cannot in some way be freed from its baneful ingredients. In other words, whether it cannot be *de-camphorated* and *de-nitrated* without destroying its advantageous features, especially its transparency and flexibility.

With a view of testing the possibility of this we have made a few rough experiments, but not with any very decisive result, at any rate so far as success is concerned, but rather the opposite. With a view of removing, if possible, the camphor, a sheet of celluloid was digested with ordinary methylated alcohol, which though at first producing no apparent result, was found in the course of a few hours to have *completely* dissolved it. Here, then, there is no possibility of dissolving out the camphor since the latter lends its aid to the alcohol in dissolving the pyroxyline.

Another sheet accurately weighed (like the last) was submitted to the heat of about 180° Fabr. in a gas oven for a period of twelve hours; at the end of that time it was physically changed to the extent of being badly curled and crumpled by the heat, though that might possibly be remedied by proper precautions. But the loss in weight after twelve hours "stoving" did not amount to *one tenth of one per cent.* on the total weight. So here, again, there does not appear much hope of driving off the camphor in vapour without hopelessly spoiling the material.

Of a number of experiments in de-nitrating, one may be specially mentioned. If the celluloid be immersed in strong concentrated sulphuric acid no apparent action takes place, but if an equal volume of water be added, the sudden and intense heat evolved causes a deep yellow colouration of both celluloid and liquid, and the evolution of a powerful empyreumatic mixed up, with which camphor is plainly recognisable. After a very short time the action ceases and the colour leaves the solution.

If the celluloid be now taken out, washed, and dried, it will be found to have lost considerably in weight and to have had its surface eaten away irregularly, or corroded in much the same way as glass when treated with dilute hydrofluoric acid. Returned to the dilute sulphuric acid and boiled, no further action takes place until ebullition has gone on for some time, when the liquid commences to turn yellow, but the colour at first quickly disappears on stirring. Gradually, however, it becomes stronger and more persistent, and at the same time strong nitrous fumes are given off, these being apparently the cause of the yellowing. Finally, the colour becomes brown, and the celluloid dissolves entirely, forming a deep brown solution.

Now this seems to prove that *as celluloid* the substance for a long time resists even boiling sulphuric acid, but gradually it is de-nitrated, and then *as cellulose* is carbonised and destroyed by the acid. Thus the possibility of de-nitration is proved, but whether it can be done practically without destruction is a question.

If this can be accomplished, one at least of the possible weak points in celluloid will be removed.

NEGLECTED PROCESSES—THE ALBUMEN PROCESS.

The albumen process may now be considered as being practically an obsolete one, notwithstanding that by its aid have been produced results which for rapidity in the case of negatives, and excellence in quality in the case of transparencies, have never yet been surpassed. The albumen was really the first glass process for negatives. This process was—we are now speaking in the past tense—essentially a slow one, as most will admit when we say that it was slower than either the calotype or the wax-paper processes. From twenty-minutes

to three quarters of an hour with the lenses then in use—single landscape lenses with an aperture of $f/20$ to $f/30$ —was a very general exposure. With regard to the quality of the negatives yielded, they were fully equal to those by any of the modern methods. Many of our older readers will, doubtless, well remember the very fine series of views by McPherson, of Rome, taken on plates eighteen by fifteen inches or larger. Although the albumen process, as ordinarily worked, was undoubtedly slow, yet, with certain modifications, it was exceedingly rapid. As an example of this, the late Mr. H. Fox Talbot, at the Royal Institution in 1851, made one of the most rapid exposures on record. It was this: Some printed matter was pasted on the periphery of a wheel and the image focussed in the camera. The wheel was then set in rapid motion, and the exposure made by the instantaneous discharge of a Leyden battery. The letters were reproduced perfectly sharp and well defined in the negative.

The albumen process was troublesome in its manipulations, and on the introduction of collodion, with its greater sensitiveness, was, so far as negatives were concerned, quickly superseded. However, it continued to be extensively used, commercially, for stereoscopic transparencies. There always has been a certain amount of prejudice against the albumen process by amateurs, on account of the supposed difficulties in its manipulations. It is quite true that in the earliest method of preparing the plates it was very troublesome, inasmuch as the plates had to be dried in a horizontal position. Albumen does not set like gelatine, hence, in order to obtain an uniform coating, the glasses had to be retained accurately levelled until they were perfectly dry. Added to this, the albumen while in a moist condition appeared to have an extraordinary affinity for dust, any particle of which would produce a spot or comet in the finished picture. It was found, however, that this difficulty could be overcome provided the plates were first coated with a substratum of collodion and washed prior to the application of the albumen. The plates could then be dried in a vertical position and an even film still secured. Furthermore, if any particle of foreign matter did happen to settle on the plate it was forced, as it were, through the albumen into the collodion film, where it remained inert.

For the last quarter of a century, or more, the albumen process has always been worked with this modification. About fifteen or sixteen years ago it may be mentioned that this, even then, antiquated process was vended as a "secret process" for making enlargements, the secret being the making of albumen transparencies for enlarging from. Few, we believe, ever worked this method much in practice.

As we remarked at the commencement, transparencies by the albumen process are still unsurpassed by those of any other, and it is in this direction that the process has mainly been employed since the introduction of collodion. The famous stereoscopic slides of the late M. Ferrier, made more than thirty years ago, are as good as, if not better than any that are made now, notwithstanding all the modern improvements in photography. Indeed, even now albumen transparencies are looked upon as the standard of perfection, for it is seldom that more is claimed for any process than "that it is nearly, or quite, as good as albumen"—never that it is superior.

How, then, it may well be asked, if this process yields such unrivalled results, that it is so little used? The answer is simple. The process, like many others, requires some little experience in order to obtain the best results, coupled with the

fact that it is more troublesome than most other processes to work, as will be seen from the following brief description. Here we recur to the present tense, inasmuch as albumen transparencies, both for the stereoscope and lantern, are still made commercially, though on a somewhat limited scale.

A glass plate, after being carefully cleaned, is coated with iodised collodion of a somewhat porous or rotten character. It is then washed in water to remove the ether, alcohol, and iodide. After draining, the iodised albumen is poured on and allowed to soak well into the film; the plate is then reared on end to dry. By the way, all these operations may be conducted in open daylight. The collodion, it may be mentioned, acts purely mechanically, and takes no part in the formation of the image. The plate, when dry, is sensitised in a silver bath, strongly acidified with acetic acid; forty-five grains of nitrate of silver and forty-five minims of acetic acid to the ounce of water are the proportions usually adopted. The plate is then washed and again dried. The exposure is generally made by contact printing. In the earlier days of the process the development was by means of gallic acid, but the more modern method is with acid "pyro," used warm. After fixing in hyposulphite of soda the image is toned with gold to the colour desired.

The principal charm in albumen transparencies is the extreme brilliancy and transparency of the shadows. Indeed, the image partakes more of the character of a stain than an actual deposit. So transparent are the shadows of a good albumen picture that printed matter can be read through the deepest ones.

From the above brief description of the process it will be seen that, compared with such processes as the wet collodion, or the collodio-bromide, the albumen, though not really difficult to work, is troublesome. And now that such excellent, ready-prepared, gelatine plates specially made for transparencies are regular articles of commerce, we fear that the albumen process, notwithstanding its excellence, stands but a very meagre chance of resuscitation, at least by modern amateurs.

A PARAGRAPH pregnant with instruction to astronomers and interest to photographers appears in a recent number of the *English Mechanic*, and, as it bears upon repeatedly-given remarks of our own in a similar direction, we here give its substance. "Recent controversy in connexion with astronomical drawings compels the observation that it would be better if photography were more extensively utilised. Astronomers draw what they see as faithfully as possible, but it is clear that they do not all see alike, even when observing at the same time. Dr. Boeddicker has recently issued a series of drawings of Jupiter made with the aid of the three-feet reflector at Birr Castle, and he is about to publish a drawing of the Milky Way, which has been reproduced by a photo-mechanical process; but it would be better, when possible, to photograph direct, and we expect that considerable advances will be made in astronomical photography before the century comes to an end."

According to its inventor, the Eiffel Tower will be able to furnish a kind of scientific workshop of a general-utility character suitable for astronomical, chemical, meteorological, and a variety of other purposes too numerous to mention. Thus, in an article in the current number of the *New Review* he says, "I may even go so far as to say that there are few scientific men who do not hope at this moment to carry out, by the help of the tower, some experiment connected more especially with their own investigations." This really is carrying enthusiasm to a very high pitch. M. Eiffel even informs us that physiological experiments of the deepest interest are to be carried on there, but, as these are foreign to our province, we do no more than allude to them.

It is, however, difficult to believe that, even at an elevation of a thousand feet, photo-astronomical work could be satisfactorily carried on in the midst of a populous district and in the immediate neighbourhood of a vast city.

THE photographing of clouds and such-like meteorological work is to be undertaken in the tower laboratories, and we should imagine will be very satisfactorily performed. The question arises, Would cloud photographs specially taken for photographers' use, and which would practically have a clear, unbroken horizon, be of value for printing-in skies? We are inclined to believe that the conditions would be too far removed from those governing the clouds taken along with a landscape from *terra firma*, and so instrumental in producing illegitimate effects. All the same, a contrary opinion may be held by others, and we should not be surprised to find upon the market ere long "Eiffel cloud negatives."

SOME little time ago we announced that Mr. V. H. Veley had shown that pure silver was insoluble in pure nitric acid, the presence of nitrous acid being a necessary concomitant of the act of solution. In the last number of the *Chemical News* Messrs. C. F. Cross and E. J. Bevan have, as bearing upon the same problem, given the results of some experimental work touching the necessity of nitrous acid being present in order to obtain certain effects hitherto associated with nitric acid alone. One of these experiments was the solution of copper: a given quantity dissolved in four hours in a certain quantity of nitric acid, but when nitrous acid was eliminated only one per cent. of the amount was taken up in the time.

THE effect of the acids on jute fibre was tried, the nitrous acid being eliminated by adding urea to the liquid; it had a most marked effect, the weight of the product after treatment increasing in proportion as the urea present was increased; but when this fibre, and also cotton, were treated in the usual manner for making gun-cotton or pyroxyline the action of the addition was absolutely *nil*.

REFERRING to the solubility of ordinary glass, such as is used in the laboratory and for household purposes, an interesting fact has been noted by a recently deceased well-known contributor to the above-named journal. He found that most of the glass vessels in his laboratory, not only those which by their clouded surface showed the action of a solvent, but also the clear-looking glasses not apparently acted upon at all, turned to a rich red colour when the phenolphthalein test was applied. That glass should not only dissolve but in sufficient quantity to colour test paper is very remarkable, and shows that this action may constitute a factor of greater importance in matters photographic than has hitherto been calculated.

A THEORETICAL reply has, in a communication to the Berlin Physical Society, been given by Professor Helmholtz to the question whether gas burnt in the ordinary manner at burner is not a more economical source of light than the same gas burnt as a fuel in an electro-motor for the production of glow lamps. The result he arrived at was that it was far more economical to use the gases for driving a dynamo which supplies incandescent lamps, and to utilise the energy radiated from the latter, than to burn the gases and utilise the energy which is radiated out from their non-luminous flames.

PHOTOGRAPHIC INDUSTRIES.—II.

THE FACTORIES OF THE LONDON STEREOSCOPIC COMPANY, LIMITED.

NOTHING short of personal inspection and observation can serve to convey an adequate idea of the nature, extent, and ramifications of some of our photographic industrial establishments. The force of this truth we experienced when, a few days ago, and under the wardenship of Mr. Mitchell, the general manager, we made a tour of inspection through the more purely industrial and manufacturing *ateliers* of the London Stereoscopic and Photographic Company,

Limited. This establishment consists of a congeries of buildings, all, however, connected with each other, and is situated on one of the heights to the north of New Southgate Railway Station, where the distressing fogs and darkness so peculiar to our great metropolis but rarely extend. The fact that this is not the only photographic industry located in the northern suburbs of London speaks for the favourable meteorological conditions which there prevail.

The first room we visited is that devoted to the registration of negatives from which prints may at any moment be demanded. These are all classified in a systematic manner. Are they views? It only suffices to know in which county, or in what country, any such view has been taken, and a book of reference is at hand immediately from which is ascertained all about it—its nature, size, and (what is of equal importance) its place on the shelves of the negative stock room. It is in the portraits of what are designated "celebrities" that the *embarras de richesses* is most strikingly apparent—and in what a monster album are these celebrities contained! No attempt here to trim and square them off neatly and nicely—a head, a face only without a head, and sometimes even only a piece of a face, suffices for the distinguishing or salient points by which a portrait is distinguished from some fellow-portrait of the same individual. Fame is the key which admits to this registry, and ensures those who are thus crowned a place in its pages where they may rub shoulders with the members of the Royal family, the favourites of the footlights, the leaders of the Salvation Army, men of mark in the worlds of politics, literature, religion, science, and art. And as they are entered in the registry-book in the order in which they are taken, all attempts at classification would be futile in such an album. Hence we have in contiguity Mary Anderson, the Earl of Fife, General Booth, the Speaker of the House of Commons, G. R. Sims, "Mary Jane," Mr. Gladstone, Archbishops, "bruisers," and Indian Princes—in short, all who have been heralded by the trump of fame.

Classification of the orders as they are received in the works is greatly aided by the fact that each department employs a special colour of paper in its order forms, and a special factory department is relegated to amateur in contradistinction to professional work.

In the silver printing department about two hundred sheets of albumenised paper are used daily. These are sensitised each morning of the day on which they are to be used. The printing room is one of great length. It consists of a central chamber in which the frames are charged and then run out through a series of little windows on each side to the printers, who expose on tables in wings adjoining this central room. The vignetting masks, we observed, are all made of brown paper edged with cotton wool to ensure softness. The toning and fixing room is very capacious, and well fitted with both slate and wooden trays and tanks. Acetate toning is employed. The system for washing the prints is very complete. On removal from the hypo tanks they are transferred to one of tepid water, which is constantly changing, from which they are removed to others, in which they are subjected to a prolonged washing in thirty changes of water at the ordinary temperature, the tanks being emptied and refilled by automatic action.

The trimming and mounting room is tenanted by a whole army of happy and contented-looking girls; and here we appreciated the great value of the system which prevails in this great establishment, for in the great variety of mounts which must necessarily be used in connexion with a number of branches no hitch was apparent, but each print was relegated to its specially "imprinted" mount. The trimming guides are made of stiff card, so constructed that the knife runs beyond the cross-cut each operation, thus securing sharp corners. The mountants employed are gelatine and starch, both freshly made.

One room is devoted to the storage of chemicals. On its shelves are to be seen many gallons of ether, absolute alcohol, and all the other fluids and solids appertaining to photographic manufacture and practice.

Collo type printing is here carried on upon a very large scale, as may readily be understood; a separate room is devoted to the preparation of the printing plates, which are in some instances large, being 36 x 27 inches. Here we witnessed the coating and drying of these plates. After exposure they are placed vertically in water tanks in order to the removal of the unaltered bichromate, their duration in the water being from four to six hours. The printing is effected on

three large machines which are driven by engine-power and are automatic in action. In addition to these there are three hand presses for proofs and small jobs. On one of the large plates as many as twenty-four small negatives may be laid down and printed at a time. In this room also is a guillotine, the knife of which is thirty inches.

The temperature in this room is very accurately maintained by means of a blower on the one hand and twelve rows of hot-water pipes on the other; and both in this and in other rooms in which gelatine forms a factor in the operations, not only the heat but the moisture in the air is carefully adjusted, several hygrometers of the wet and dry bulb thermometer variety suspended around serving as indicators. A jet of steam projected from a vapouriser into the air restores it to the working equilibrium when too dry. In connexion with the large printing presses we observed some ingenious appliances by means of belts working over cone-shaped shaft pulleys, by which any definite degree of speed could be imparted to each or any of the steam presses. The inking rollers are formed of leather and composition.

Seeing that gas, by way of local heating and otherwise, plays an important part in this factory, it has been found necessary to regulate its pressure; for previous to this having been done the quantity required at the works influenced in a serious measure that necessary for the private residences in the vicinity. A Siemens' dynamo serves as the means by which illumination is obtained.

In the Woodbury printing department there are thirty printing presses. The reliefs are made by a Tangye hydraulic press, 11 x 9, giving a pressure of five hundred tons. There is another of a similar nature, but of less dimensions, for smaller reliefs; its pressure is two hundred and fifty tons. In a room adjoining, the paper is prepared for Woodbury printing. This is passed through rollers no fewer than thirteen times to impart the necessary smoothness and quality.

Carbon printing, both on paper and opal, is extensively carried on. During the late "craze" for opal prints, no fewer than two hundred thousand were supplied by this Company for two houses alone.

(To be concluded in our next.)

ECHOES.

It is a very sensible *Suggestion to Plate Makers* made in a leading article last week, namely, that every plate before being sent out should be branded in some manner, so that its maker may be identified at any future time. It is a suggestion, too, of very easy application in the case of plates that are to be used for portraiture, as in such cases a large area of the sensitive surface is generally unused. But what about landscape plates which are usually printed "up to the edges?" Surely the writer has overlooked the rather important circumstance that a label, a dab of paint, or a series of "diamonds, squares, triangles, circles, &c. &c.," might rather interfere with the beauty of the prints.

It is certainly desirable to know, before commencing to develop, what and whose plate is under treatment, and most careful operators do know. It is rather hard, though, to throw the onus upon the plate makers of preventing accidents from sheer carelessness on the part of the users of the plates.

It is desirable, I say, to possess the knowledge, but far from absolutely necessary, as I found on one occasion some years ago. Having exposed a dozen plates from a Mare's changing box, one half of which were Wratten's "Ordinary," the remainder their "Instantaneous," the two kinds being duly marked, I found that owing to the fact of the plates being inserted by the *bottom* of the box, I had, in using them from the top, got their relative positions mixed, and exposed the slow plates for the more rapid subjects, and *vice versa*. With the knowledge of my error in view, I set to work to develop, and did not lose a single negative; further than that, and showing the sterling quality of the plates, there was not one that might not have had its "best" exposure.

Mr. Edward Dunmore is an "old photographic hand," and the advice that he has to give is always good. Young beginners, aye, and older stagers, may read his article on *Care* with advantage, for nothing more than *care* helps in the earlier stages to make a good photographer. But I cannot help thinking that there is a tendency to make "care" the one thing needful to the exclusion of other equally important qualities. "When you see a man scrupulously

fastidious about the condition of his camera and lens, it is an outward and visible sign that he will be careful about his work generally." So says Mr. Dunmore in the opening sentence of his dissertation, but is it so?

I knew many years ago an amateur who might have been the very instance Mr. Dunmore had in view. He kept his three lenses in little velvet bags, which again packed into a cosy padded leather case, and his camera had a macintosh covering to envelop it completely, with a slit for the slide and shutter, so that a chance shower of rain should not spoil its beauty. He had it French polished, I believe, once a year, at least it used to be said so, and certainly it always looked as if it were just "out of the shop," and was the chief feature of our outdoor gatherings—the pride of our Society. But neither I nor any one else ever saw a picture by this careful artist, though he was constantly exhibiting "something," and wanting to know what was the matter with it; in fact, all his "care" seemed to be exhausted on the camera and lens.

A contemporary friend and member of the same Society was another peculiar example of "care," but his mania was chiefly exhibited in connexion with the chemical part of the proceedings. A separate measure or glass for every operation; a separate dish, when dishes were necessary of course—very laudable if not absolutely needful arrangements. But there was also a special place for each bottle, glass, dish, &c., his dark room contained, and each had to be returned to its proper place every time it was used. You must not have the developing solutions on the table while intensifying, and *vice versa*; develop, clear away the paraphernalia, bring down the intensifying "kit," clear that away, fix, &c.; then commence the next plate *de novo*. This gentleman rarely developed a plate himself, never if he could get a friend to spend the evening with him and do it for him, and I can speak feelingly of the pleasure his friends experienced in conforming to his rules, which were like the laws of the Medes and Persians, and changed not for any one.

On the other hand, I have known a good many photographers, both amateur and professional, whose names are as household words both as writers on photography and as successful exhibitors, but I cannot say that I have ever been very deeply impressed by the exhibition of any undue amount of care in their general arrangements—perhaps, if the truth be told, rather the opposite. I remember once, at a public demonstration of a new method of emulsion making, the demonstrator, one of the leading writers of the day, used the palm of his hand in place of a cork in shaking up the bottle of emulsion, and then, quite as a matter of course, proceeded to wipe it, not on his coat tails, but on "the domain that there adjacent lies," much to the amusement of some of the audience. The fact is, care wants to be used, like everything else, "with brains," but brains of the right sort get on fairly well with a very moderate garnishing of what is called care.

It seems, after all, that the "Ipswich phantom photograph" was not so ridiculous a matter as photographers were too ready to assume, but rather a *boni fide* spirit prophecy. So, at least, I gather from the report extracted from the *East Anglian Daily Times* last week. This is a new rôle for "the spirits" to play, to photograph a dead person two months before death on the very spot of the occurrence. How science is advancing even in spirit land! What a fine plot this would make for a novel from the Philistine point of view! Here is the "argument." An enthusiastic amateur finds a mysterious and ghostly figure on one of his negatives, the said figure not having been present when the picture was taken. He is certain it is of spirit origin, and after careful thought elaborates the theory that it is a prophetic warning of a coming crime, but is terribly ridiculed for his pains. Exasperated at this, he is determined that his theory shall be established, and so commits, or "procures to be committed," a murder, and deposits the victim's corpse on the very spot on which it appeared in the photograph. Carefully and skilfully "worked up" by a competent "penny dreadful" artist this should take well and would dramatise beautifully.

JUNUS.

THE WHOLE ART OF PHOTOGRAPHY.

VII.—FIXING, WASHING, AND DRYING NEGATIVES.

In fixing a gelatine negative it cannot be too strongly impressed upon the tyro that it is not fixed immediately upon the disappearance of the bromide under the action of the hyposulphite of soda solution,

the strength of which should be about four ounces to the pint of water.

The first action of the hypo upon the silver bromide is to convert it into silver hyposulphite, which, being a clear, transparent salt, is apt to induce the idea that because the opaline silver has disappeared therefore fixing has been effected, seeing it is no longer visible. But the invisible silver hyposulphite still remains, and as its presence in the film would ensure a bad discolouration at a subsequent period, and as it cannot be removed by any amount of washing with water, it must be dissolved out by a suitable solvent. It is fortunate that the same agent by which it was formed is also the best solvent for it, hence all that is necessary to ensure its removal is to allow the plate to remain in the hypo solution for a short time after the last visible traces of silver have disappeared, this being ascertained by raising up the plate and examining the negative through the glass.

Here it may be observed that some makes of plates fix in infinitely shorter time than others. We have some plates the bromide in which disappears after a duration of half a minute in the hypo solution; but we have also some which require about a quarter of an hour to effect this end.

In washing the negative to remove the fixing salt, if one has not a proper washing apparatus—which is always best—it can be effected in a thorough manner either by allowing a gentle spray of water to fall upon the surface for half an hour, more or less, according to the permeability of the film, or by placing it face down in a basin of water under such circumstances that it is supported by the corners at some distance from the bottom. For small plates the saucers belonging to breakfast cups answer well. Care must be taken to change the water frequently. These, however, are but makeshifts, although effective enough, in the absence of properly constructed washing troughs, of which there are numerous forms in the market.

To dry a gelatine negative is not the easy thing that appertains to one on collodion, which it is only necessary to hold before a fire for a few seconds. Heat melts gelatine in presence of moisture, therefore it must not be thought of. By rearing the negative up on a slip of blotting paper to absorb the drainings, a few hours suffice to find it quite dried. But it is often not expedient to wait so long a time for the drying of a negative. By what means, then, can it be hastened?

The first thing to do is to get rid of the surface water. To do so lay the negative back down upon a sheet of blotting paper, and spread over the face one or two thicknesses of clean cambric, or a thick absorbent sheet of blotting paper, and apply gentle pressure all over the surface. It is of no consequence that markings of the textile fabric be impressed upon the soft gelatine; they eventually become levelled and disappear.

The moisture having thus been minimised, place the negative in a current of air admitted through a partially open window, and in from five to fifteen minutes, according to the dryness and force of the air, it will be quite dry.

It is well known that water and alcohol have a great affinity for each other. A method we have often tried, although inferior to the one just described, consists in laying the negative in a vessel of alcohol and causing it to flow in waves over the surface. Very soon the water is displaced from the film, the alcohol taking its place. The plate thus treated dries quickly—nay, it may even be dried by heat, although this, in consequence of a possible modicum of water still remaining in the interstices of the gelatine, is rather risky.

It is always well to warm the plate after it has been air-dried, so as to ensure its complete desiccation. After this it may be varnished, if it is considered worthy of being kept for a long period, although it is not necessary when only a few prints are desired.

DINNER TO MR. THOMAS BOLAS.

On Tuesday evening Mr. Thomas Bolas was entertained at dinner in the Holborn Restaurant by several gentlemen connected with journalism and photography, the occasion being his severance from the editorship of the *Photographic News*, which post he has filled since 1880. Mr. J. Traill Taylor presided, the vice-chair being occupied by Mr. E. W. Foxlee.

Letters and telegrams expressive of their sympathy with the meeting, with regret for inability to be present, were read from Messrs. T. R. Dallmeyer, W. B. Bolton, H. M. Hastings (F.C.S.), and others.

The Chairman, in proposing the toast of the evening, said that he could speak of Mr. Bolas from the vantage-ground of a very long acquaintanceship, dating anterior to that gentleman's connexion with the *News*, and he could testify to his honest and straightforward character. As a rival editor he had invariably found him honourable and courteous, and although they did not think alike on all topics, there never had arisen the semblance of friction to disturb their personal friendship. He asked them to honour their guest in full bumpers.

Mr. W. E. Debenham could endorse every word in praise of Mr. Bolas uttered by the Chairman. He, too, had known him many years, and highly appreciated his abilities.

Mr. William Bedford was in very strong sympathy with Mr. Bolas, who had invariably fought the battle for the photographer as against others; he was upright, unreserved, and plain-spoken, and he wished him a cordial success in his new undertaking.

Mr. Foxlee was, perhaps, better able to testify to Mr. Bolas's good qualities than any one present, as he had known him much longer than they, and he could merely echo all that had been said in his favour, but he would do that in the strongest manner possible.

Similar sentiments were expressed by Mr. F. A. Bridge, Mr. J. J. Briginshaw, Mr. G. F. Williams, Mr. E. Dunmore, Mr. E. Clifton, and Mr. Alexander Cowan.

Mr. Bolas made a suitable acknowledgment. He expressed his high appreciation of the compliment paid by such a representative body of gentlemen as those present.

Mr. Foxlee, in proposing the health of the Chairman, called attention to the fact that Mr. Taylor had just completed a quarter of a century since he first took the Editor's chair of THE BRITISH JOURNAL OF PHOTOGRAPHY. He first made his acquaintance at the presentation made to Mr. George Shadbolt, the former editor, on his retirement from journalism twenty-five years ago, and personal friendship had existed ever since; a similar friendship he believed ruled with all those present.

Several remarks were made *apropos* of this, and after a pleasant evening the party broke up at a late hour.

MOUNTING AND THE SURFACES OF PRINTS.

It is a gratifying proof of the interest shown in photographic matters by our modern practitioners that old processes are being revived, almost unearthed, we might say, and worked side by side with the most recent refinements and improvements.

An instance of this, which has just come under our notice, is the re-introduction of a well-known process for obtaining prints on rough-surfaced paper, the details being as follows: Drawing paper is salted with a proper salting solution containing enough gelatine to size the surface, and is afterwards sensitised with ammonio-nitrate of silver applied with a cotton brush. The paper is not fumed, but simply well dried and printed as usual. It is toned in a carbonate of soda bath and fixed. It is mentioned as a strong point in favour of this process that "tones resembling those of the platinum print may be obtained." We can strongly recommend the process to those whose artistic feelings are wounded at the glossy surfaces of the albumen, gelatino-chloride, collodio-chloride prints, &c. But let us add that the process will be found most suitable for subjects that present bold contrasts of light and shade without much fine detail. In portraiture, for example, we should select a negative lighted in the so-called "Rembrandt" manner, and one of large size rather than a small one full of delicate detail.

The surface, or rather the absence of surface, of prints thus made will depend upon the grade of paper selected. Whatman's papers have been recommended as possessing every requisite quality. Now, in common with the platinum, plain silver, and blue prints, these prints on drawing paper offer the great advantage over those made on albumen, gelatino-chloride, &c., that they are *non-contractile*, and may be easily mounted without risk of injury to the surface of the picture. It is a matter of common observation among those who have had experience in printing on albumenised paper, that after the print is finished the surface is more or less covered with minute cracks. In some cases this constitutes a very unsightly defect. If the paper is highly albumenised, and the weather when the prints are made very cold and dry, and the prints hurriedly dried in a hot room after removal from the last wash waters, it may be impossible to obtain a good smooth surface free from cracks, even if the print be thoroughly rolled.

As a general thing, however, the commercial brands of albumenised paper have too little albumen on the surface to behave in this manner, and there is rather a general want of brilliancy than any defect, owing to a too heavily albumenised surface.

Should any of our readers be troubled in this manner, they will be able to improve matters by adding a little pure glycerine to the last wash. The exact quantity to be added, of course, would have to be determined by experiment: an ounce to the quart might be used to start with. After the prints have been thoroughly soaked in this they should be lifted out, placed together back to back, and dried in this position by means of spring clothes clips. As each print exerts traction upon the other, both will dry quite flat, and the small quantity of glycerine will remove the obstinate tendency to curl and prevent the albumen surface from becoming unduly dry and cracking.

Some operators insist that the prints be mounted while still wet, in order to prevent cracking of the surface, but this necessitates that the prints be finally trimmed before the washings and handlings, which seldom fail to fray and disfigure the neatness of the corners and edges. The best reason for pursuing this plan, to our minds, would be that the mounted print could be passed through the rolling press while the albumen surface still retained sufficient moisture to render it pliable and compressible under the heavy pressure. If the prints were first dried and then re-wetted before mounting, it is evident that the same end would not be effected.

Any one who has had to mount large batches of prints knows very well how much the work is expedited by wetting them. Those nearly of a size are brought together face down and laid on a sheet of glass. A large soft towel is dabbed over the back of each print until the superfluous moisture is removed, and the gelatine then quickly laid on with a flat hog's-hair blender. The card being ready, all that remains to be done is to pass the point of a knife under the upper print, lift it off, and apply it to the card. A clean sheet of blotting paper is then laid over, and a few passes with the hand finish the operation. The print, it will be seen, requires no holding with the hand during the pasting, and there is no possibility of the gelatine getting on the surface of any of the other prints. The cards, however, will always cockle badly when the prints are thus mounted, unless dried under pressure between blotting papers.

The surface of the aristotype and other papers in which gelatine is employed in sufficient amount to give great gloss is by far more difficult to manage than the albumen surface. Authorities are somewhat divided as to the manner in which the finished print should be treated. Dr. J. Schnauss, in the *Archiv*, says, "I have abandoned the practice of mounting prints wet, whether made with collodion or gelatine, but particularly the latter. I do not advise the employing of a warm gelatine solution for mounting gelatine prints, because the gelatine surface becomes very much softened and so sticky that it requires the greatest care to finish the work without injury to the film. In my hands the best method has been to dry the picture as flat as possible and mount it with a rather thin, cold paste made of rice starch. The most brilliant aristotype prints may be mounted in this manner, as well as those on collodio-chloride paper."

Dr. Schnauss then proceeds to say that prints on albumenised paper should be mounted wet. We have already sufficiently discussed this point, but let us add that neat results may be had when prints are to be mounted in albums if they are first *slightly rolled*, not too much, so as to crush the substance of the paper, and then mounted in with the well-known alcoholic solution of gelatine. By placing a sheet of clean thick blotting paper between each pair of leaves and keeping the album under pressure, there will be little or no cockling of the leaves when the work is finished.

ELLERSLIE WALLACE.

—*American Journal of Photography.*

COLOURED PHOTOGRAPHS.

III.

JUDGED by a liberal mind, there will be little difficulty in deciding that there is more than a very strong family likeness between *pure art* (if I may be allowed to so express myself) and the *photographic art*. The same fundamental rules of art must guide us in both cases, in the general composition, lighting arrangement and adjustment of accessories, the keeping of the latter in judicious yet complementary subordination, &c.—as we would in a *picture*, so should we do in a *photograph*. The same fine feeling should actuate the photographic operator in his glass room that inspires the artist in his studio. Take my word for it, there is a very much closer affinity between the camera and the easel than a mere first-cousinship in art.

As a starting-point, we should fix well upon our minds that in all pictures there should be at least one leading or predominant light, a

point of attraction as it were, that will at once catch the eye and arrest the attention, and to which all others should be subordinate. It naturally suggests itself that in portraiture this leading point of attraction is the face, for upon it depends the value and interest of the entire picture. Everything should give place to the face; there should be no obtrusive accessory, no too apparent dash of colour, for such, or any other distracting influence that may be in a picture, must unhesitatingly be set down as a fault. By this I do not wish to convey the idea that the face must be the *only* point of light or attraction. Quite the reverse: lights may be repeated in various places and ways throughout the picture, but in a subdued degree. Treated so they will enhance the general effect of the picture, impart to it a life and airiness, give tone and importance, whereas without them a sense of heaviness and lack of interest might pervade the picture. Of course in all these matters individual judgment must be used, as no hard-and-fast lines can be laid down. In many cases, for example, it might be found not only advisable, but absolutely necessary, to relieve a heavy mass of deep shadow by the infusion of a little light. In this regard the artist has a very powerful advantage over the photographer. The latter is obliged to effect this result by letting in *real* light (very difficult to govern and direct as one would wish), which may in many ways interfere disadvantageously with the rest of the picture; while the former holds complete control over the various means at his disposal to accomplish such an effect. In the construction of a picture, where there may be a number of accessories, the photographer will assuredly place such coloured articles as will catch the light more than the surrounding objects, or whose action qualities will produce a different degree of intensity, and so impart a certain degree of transparency to what otherwise would be meaningless masses of dark shadow. Still, as I said, there are many difficulties in the way, while the painter, by a judicious and harmonious blending of colour, can secure the desired effect, and yet not alter in the least the general tone and importance of his shadow. It is always a matter of serious importance to treat the deepest masses of shadow in such a manner that they will not appear too *heavy*. In doing so, however, we must not detract from their importance, as failing to preserve them sufficiently dominant would be to seriously imperil the two very essential qualities of a good picture—balance and solidity.

Bearing this in mind, when arranging a portrait (more particularly three-quarter or full-length), the masses of shadow—that is, those portions which suggest weight—should be located at the base, or lower portion of the picture. This applies as much to colour as to form. Take, as an example, the production of a three-quarter or full-length portrait of a gentleman. Now, suppose we paint or photograph him against a plain background, the light and everything else so arranged that it will present an equal tone all over, and what will be the effect? A most uncomfortable and absurd picture. An uncultured eye may look at it, feel there is something wrong—he cannot detect where the trouble lies—but his feeling of dissatisfaction is palpable.

Now, what can we do with such a picture to render it satisfactory? The photographer, unless he calls in artistic aid, must needs take the picture again, and in doing so take the necessary means to produce the effects which the artist carries out as follows. It is breadth of base that is the main fault—there is a lack of solidity and balance, and this must be altered. We must introduce a little shadow in the lower portion of our picture, which will be found to materially steady it. The introduction of accessories, such as a stick or an umbrella, judiciously taken advantage of, will also add to the solidity and steadiness of the figure. The idea is imparted of support to the body, which must naturally in turn carry with it the effect of a greater breadth of base. To the thoughtful photographer this does not offer much trouble, and to the artist still less, for he can so arrange that his darker masses of shadow will naturally incline to the bottom or base of the picture, and thus secure that equilibrium or balance without which success is impossible.

It is essential that these and all similar effects should be conceived and carried out in such a manner as not to unduly attract the eye. That they should appear *natural* must be ever our first endeavour. To appear *artificial* would be to considerably mar the beauty of our picture, as well as to expose the intention of an artist, a result which would very seriously discount the advantages otherwise gained.

To the beginner or amateur who has made up his mind to acquire a general knowledge of the primary rules for the artistic composition and grouping of portraiture, be it in the photographic studio or on the painter's canvas, the form known as *pyramidal* seems to be the most general favourite. It seems to him the easiest, as, perhaps, it is the least complicated. I have nothing whatever to urge against its adoption, but I can assure you it requires no small amount of artistic knowledge and skill to carry it through *successfully*. The great

danger is that we let the means by which we gain our effects be too palpable. This would give our composition the appearance of being *strained*—a fatal error. At first sight all this will not appear very striking; but, believe me, however easy it may appear to be to carry out this style of composition, it is not so. I therefore warn the beginner that he must work carefully if he desires to gain a mastery over it. One must cultivate a keen artistic appreciation as a sure means of success in this form of composition. The labour expended in gaining a thorough knowledge of the various forms of composition will be more than repaid in the working out of your profession in after years. We will have to produce groups of the most awkward numbers and disproportionate subjects, such as would many times almost baffle a Sir Frederick Leighton to realise grace of composition in making a picture of them. I feel sure any operator of a few years' standing will bear me out in this regard.

Next to form comes *contrast*. This is a most important element in every form of pictorial effect: contrast as regards the drawing or leading lines in your picture, contrast as regards tones—be they in colour or merely light and shade. For example, the value and natural grace of *curved lines* can not only be made forcibly apparent, but be very considerably augmented, by the judicious placing of *straight lines* producing *contrast*. If this be true as regards *lines*, how much more so must it be when we consider colour. I feel inclined to say that a good half of the beauty of any picture is the successful carrying out of contrast as affected by colour, the value of a colour being enhanced or neutralised by its juxtaposition to others of a more or less complementary nature.

Vigour, relief, brilliancy, and above all a general harmony, are some of the many results produced by artistic contrast and the skilful arrangement of the numerous varieties of tones. Contrast should not be harsh or abrupt, as a rule, nor should it be considered as in all cases *pictorial effect*. It may or it may not. Contrasts, badly treated, can mar a picture effectually, just as they can benefit when skilfully carried out. For instance, the bringing together of a mass of white and a mass of black (without the assistance of a half tone) will produce *contrast*, but will be devoid of any pretensions to pictorial effect. One of the grandest and most desirable qualities necessary in a picture of merit is *breadth*, and this will not be found where there are harsh and violent contrasts. In arranging the background, draperies, and accessories, therefore, we should never let black and white come in immediate proximity, and the same applies to such colours as would present a similar violent and unfriendly contrast. Black and white and similar colours (if I may be allowed to call black and white colours) of a violent or opposing nature may be necessary, and even advantageous in a picture, but their approach should be softened by such gradations as would avoid the least feeling or suggestion of harshness or crudeness.

On the judicious and artistic lighting of the model depends to an enormous extent the means of producing harmonious contrast of tones—either in colours or simply light and shade. It is, therefore, worth a moment's consideration. Avoid throwing a direct front light upon your model; such a treatment would deprive it of all relief. Unless some very special effect is sought after, the light should be thrown on the model at an angle of 45°; direct *vertical* light is bad, but the use of the *side light* is unlimited, except by the boundary of common sense. A point worth bearing in mind is that force is gained by a direct light, while softness and delicacy can only be produced by diffused light. Never try to obtain a picture by one or the other, but rather by a judicious combination of the two. Form and strength of outline may be secured by the use of the direct light, and the diffused light then step in and impart softness and quality. There are generally two things necessary in regulating the diffused light—the *pole* with which you push the curtains, and the *brains* which more or less should govern the pushing of the pole. I say this because too much diffused light will impair the quality of the shadows and result in the production of a flat and tame picture. Indeed, I repeat, to produce a really good study, full of force and vigour, and yet possessing softness and half tone, it is necessary to use the *direct* and also the diffused lights.

In *half* and *three-quarter-length* pictures many prefer plain backgrounds; by this I mean without accessories. It is advisable, however, to have them tinted in such manner as to indicate a deeper shade at the bottom than at the top; this is simply to secure balance. These pictures, so treated, although very pleasing and satisfactory, should not form our model for *full-length* portraits. The latter really require a little help in the way of accessories and general surroundings. In the arrangement of these too much care cannot be expended in seeking after a harmonious balance; each article should be selected with a distinct object, and should be in harmony with the surrounding objects, as well as with the character of the sitter.

I have seen many strange combinations in my time in this regard. Were it not that I have seen them I should be inclined to doubt the facts. Some little time ago it was nothing so very uncommon to see an article of furniture, most at home in the drawing room, enjoying, as it seemed, a short stay on the seashore. I should think every one has seen a curtain in an open-air background; I have seen a lady in evening dress photographed against some snow-capped mountains: all this is bad, and seldom occurs now, yet I know a first-rate West-end house where it occurs even now. Another favourite and less observable blunder of the thoughtless operator. I have seen balustrades painted, &c., with the light coming from the left and throwing shadows accordingly, while the sitter was lighted from the other side altogether—of course this is a pity, and should not occur, but it does.

An operator to turn out good work should have a goodly supply of accessories, as only thus can he surmount the difficulties he has to contend with in photographing some ungainly subjects. In painted backgrounds care should be taken that the sun shines on the sitter as it does on the landscape. The less form there is in a background the better—many pictures have been spoiled by shadows coming in an unfortunate place, spoiling the face or head. The carpet should not be too pronounced.

I think we have now touched upon nearly all those points which tend to giving us a really good photograph upon which we can start colouring, and we will now start on mastering the delicacies and methods for producing coloured photographs. A photograph, however good, is not like life—it is cold and lifeless; but by the skilful application of colour we can endow it with life and animation; colour can give the idea of a man's character, his occupation, and even his mind.

REDMOND BARRETT.

VARIOUS PHOTOGRAPHIC PROCESSES FOR COPYING LINE DRAWINGS, ETC.

[A Communication to the London and Provincial Photographic Association.]

WHEN I promised your esteemed Secretary (Mr. Bridge) that I would come to give a demonstration before your Society, I think I made that promise rather rashly, not thinking at the time to whom I was coming, and before whom I was about to demonstrate, and that there were gentlemen in this Society to whom I ought to look to for instruction and advice instead of my coming to attempt to teach them. But in this particular branch of photography, viz., the copying of line subjects, it may be new to some of you, and as a considerable portion of my time is occupied in this particular branch, I thought it would not be out of place to show you some of the work I have already done, and also my mode of procedure in doing it.

I may say at the outset that I do not prepare my own paper, as this can be obtained ready prepared from several photographic dealers, whose names I shall mention later on; but those who wish to prepare their own will find several formulæ in the Photographic Annuals. It is not my intention to night to advertise any particular process, but shall leave you to judge which you think the most suitable.

There are various methods by which maps, plans, tracings, &c., can be copied. First, there is the "Ferro-prussiate" process, by which copies can easily be obtained from a tracing. The operations are the most simple of any process known. After printing, the copies are merely washed or fixed in clean water, producing white lines on a blue ground. The face of the drawing is placed against the glass of the printing frame, and the prepared paper is then placed on the back of the drawing. It is advisable that the paper should be somewhat larger than the drawing, so as to leave a margin exposed to show the action of the light upon it. The exposure required in very bright sunshine varies from five to fifteen minutes, but in the very dull days of winter it may require two or three hours, or even a whole day. During the exposure to light the paper assumes various tints, from greenish blue to olive. When the exposure is complete the print is taken from the printing frame and immersed in clean water until the lines become purely white. The time required for washing occupies from five to ten minutes, but if warm water be used the result is obtained much quicker. Over washing reduces the intensity of the blue ground, but the copies darken somewhat in drying. If a line or figure has been left out by mistake on the original drawing before being copied, the same can be produced upon the printed copy by using a solution of soda and water.

The greatest drawbacks to this process are the length of time occupied in printing and the ground being blue, which make the copies unsuitable for colouring. Copies, however, can be obtained with blue lines on a white ground by this process, but a negative has first to be made. The negative print to produce this result requires at least three or four times the exposure as that by which white lines on a blue ground are produced.

Very pleasing pictures can be made by amateurs who may wish to make a fanciful experiment by printing from negatives on this paper, which can be obtained, ready prepared, from Marion & Co., Soho-square, London, and Messrs. Bemrose & Sons, London and Derby. Those who desire to prepare their own paper can do so by the use of the following formula:—

A.
Ammonia citrate of iron 1 part.
Water 5 parts.

B.
Ferricyanide of potassium 1 part.
Water 4 parts.
Mix together in equal quantities.

BLACK LINE PROCESS.

I now come to a process which is more suitable for colouring purposes than the latter, whereby black lines on a white ground are produced. The exposure required in this process is considerably less than the ferro-prussiate. The operations are as follows:—

The drawing to be copied should be on very transparent tracing paper or cloth, of a white or bluish tint; care, however, should be taken to make the lines of the drawing uniformly black, and not too fine, as the lines on the copy are rendered somewhat finer. Place the drawing in the printing frame with its face to the glass, then over it lay the sensitised paper. It is advisable that the paper should be somewhat larger than the drawing, in order to leave a margin exposed to show the action of the light upon it. The exposure is complete when the ground of the sensitised paper, which is yellow, has become a pure white, and a distinct copy of the original appears in dark yellow lines. To develop, remove the copy from the printing frame, and immerse in a gutta-percha-lined bath containing the acid solution, prepared as follows:—

Gallic acid 1 part.
Citric acid 1 "
Alum 8 parts.

Take one and a quarter ounces of the above to one gallon of water. This should be mixed in another vessel the same day it is used. Allow the copy to remain in the solution until the lines are a deep black. The same solution can be used over again for several prints, or until it becomes quite black. After development the copy must be thoroughly washed in clean cold water, frequently changed, and then hung up to dry.

BLUE LINES ON WHITE GROUND; OR, PELLET PROCESS.

The next process I wish to describe is, perhaps, more difficult and complicated than either of the two already mentioned, but its advantages are many; it can be worked in all weathers and requires no dark room. The copies can be coloured and varnished, altered and corrected; and last, but not least, they do not fade. This process is ten times quicker than any other, was invented by a well-known French chemist, M. Pellet, and was introduced into England by Mr. G. E. Chapman, 69, Victoria-street, Westminster, who is the sole licensee.

The instructions are: Place the drawing to be copied in a printing frame, and upon it a piece of the prepared paper, close the frame and expose to the light. The exposure can only be determined by constant practice and test slips. These test slips should be placed in the printing frame alongside the tracing which is being copied. These small test slips are inserted so as to remain about two-thirds inside and one-third outside the frame at the back. They can then be conveniently drawn out without opening the frame or disturbing the print.

After a time one of the test slips is drawn out and dipped in a saturated solution of yellow prussiate of potash, and its chemical action watched for from forty to fifty seconds. Should the background remain perfectly yellow, and the lines come out dark blue, the exposure has been sufficient. It is not necessary to develop the copies immediately after exposure, therefore all the printing might be done while the light is strongest (especially in winter), leaving the development until the evening or the following day. When the copy is to be developed it should be placed face downwards on a smooth board, and the edges turned up carefully, so as to form a sort of tray, three-quarters of an inch in depth. This renders the sheet more easy of manipulation, keeps stains from the back, and renders it white when developed in the prussiate bath.

The copy is now placed face downwards and floated on the prussiate bath for about thirty seconds. The operator should see that uniform contact takes place everywhere while in the solution. Raise the copy, inclining it to allow the solution to drip off one corner; then notice particularly how the lines seem to stand out.

If they do stand out, and the ground remains perfectly yellow, the development may be considered complete. After development the copy is immersed in clean water in order to check the further action of the prussiate, and then immersed face upwards in the acid bath of a ten per cent. aqueous solution of hydrochloric acid, care being taken that the entire copy, both front and back, is saturated. The surface of the copy should be worked all over carefully with a soft brush, to loosen the blue mucilage. The copy is next placed face upwards in an empty tray, and again well brushed, to get rid of the superficial mucilage, being flushed copiously at the same time with water both back and front, so as to remove all traces of the previous chemical solution.

Any blue stains on the copies may be removed or alterations made by the use of the blue solving supplied with the paper. Any blue stains on the hands may also be quickly removed by a very weak solution of hydrate of sodium. It is essential that the contents of the two chemical baths do not get mixed, or blue stains will appear. To prevent this, it is advisable to well rinse one's hands in clean water after each operation.

COPYING DRAWINGS BY THE AID OF A CAMERA.

Mechanical drawings are sometimes required to be reduced by the aid of photography with the camera. I may say the best results are to be obtained by the wet or collodion process, but very good negatives can be secured with a dry plate if properly managed. The greatest drawback with the dry plate is the probability of the fine lines on the drawing becoming clogged or veiled over during development.

But I have seen an excellent developer mentioned in THE BRITISH JOURNAL OF PHOTOGRAPHY a few months ago, which I have tried with excellent results. It may not, perhaps, be out of place to give it here for the benefit of those who, like myself, have sometimes fine subjects to copy:—

Carbonate of potassium	360 grains.
Sulphite of sodium	360 "
Water	6 ounces.

To each ounce of developer two drachms of this solution, together with thirty or forty minims of the ordinary ten per cent. solution of pyro (and sulphite) are added. The mode of development found to answer best is to soak the plate first of all in gallic acid solution (two grains to the ounce) for half minute or so, and then transfer it direct to the developer, where in about another half minute the image begins to appear. Watch carefully, and when the details in the darkest part of the picture acquire tolerable strength, add five minims of a sixty-grain bromide solution, and proceed until sufficient density is acquired.

Should matters hang fire at all, a few drops of the ordinary dilute ammonia solution may be added to freshen up the developer, but this is rarely needed if the exposure has been correct.

On the latter point a word may be said. Though the use of gallic acid does not necessarily lengthen the exposure required, it has been found better to give more than is absolutely necessary. Thus, if five seconds be sufficient to produce a perfect image under ordinary circumstances, give ten or even fifteen. The result will be quicker development and less necessity for forcing, and hence less chance of fog, stain, or filling up the lines. Six times the normal exposure has not produced any signs of the plate being overdone; indeed, it seems next to impossible to produce such a result when the gallic acid is employed in the manner described.

THOMAS SCOTTON.

JACK AND I IN NORWAY.

V.—ORMEIM, FLADMARK, HORGHEIM.

We drove on to Horgheim, where we had arranged, if we could get a convenient place, to see into our slide. A cellar under the house was placed at our service, which, after considerable planning, we were successful in making available for use. There was a window in it, and the difficulty was to get the light from it stopped out. This was one of the occasions when Jack's hammer, nails, and tacks became of indispensable service to us, for not a thing of the kind was to be procured in the hamlet for love nor money. Outside we nailed our waterproofs and rugs over the window, but the wind kept bulging and blowing them out, no matter how well we tacked them down, so we got together all the long-handled agricultural implements that we could lay hold of, and propped them up to hold the coverings, and by this means they were kept fairly steady. On opening the slide we found that the small, white, wood holder, with the brass wire spiral springs at each side (that is used to keep the film taut when winding) had come out of its place, and was rattling about loose in the bottom of the slide. The worst of the accident was that the sharp ends of the brass wire spiral had caught, and torn the last two negatives taken. The only way we could account for the holder leaving its place

was that the jolting of the stolecarré had shaken it out of its fastenings. Believing this, we were for the future most careful to look after these springs, and to fix them with more than ordinary caution before closing the slide.

After enclosing a 'new roll in the slide we came out and made an exposure on the station-house, found everything right, and drove on our way rejoicing. We stayed at Fladmark for supper, and after resting an hour or two proceeded to Ormeim. From this place our intention was to photograph the surrounding scenery, and on our way back to Naes arranged to take the most prominent features of the Romsdal Valley. We did not reach Ormeim till midnight, as it was quite light we went out and had a look round.

The Vermo Fos, or Fall, is quite near to the station-house. There is a terrace or veranda built out at the end of this inn, from which the visitor can sit and see this stupendous Fall in all its magnificence. From the top to the bottom it will be over a thousand feet; with a rush and clear fall it precipitates itself half way down the mountains, where, breaking on a rocky flat into three separate torrents, they hurry in their mad career down into the rushing river below. The constant din of falling waters fills the air, and we have to speak at the top of our voices to be heard. With this perpetual sound of many raging torrents in our ears we tumbled into bed and went to sleep. We found the Ormeim station a clean and tidy inn, and the food was plain but good.

We were out early next morning viewing the land and making notes of the points to be taken. The whole place and its surroundings commended itself to us as a very paradise of lovely bits for the camera: scenery that would not pall upon the enthusiast for weeks if he had but the time at his command. So enchanted were we with the place that the proverbial eager impatience of the amateur took possession of us, and before breakfast we started to our labour of love, and we had secured some good little studies before we were called in to *frökost*. It was really the little bits that were so beautiful here. For instance, we had a waterfall nearly opposite to the door, with part of an old wooden lade lying picturesquely half in half out of the water, a tub set on some cobble stones catching the spray from the fringe of the fall. Stray, trailing foliage twining all around, whilst the old stable with small fir trees growing from its roof stands in the near distance, and the mighty chains of hills reaching until they are lost in cloudland. No description can convey an adequate idea of such pictures, they must be seen to be appreciated—and here they may be seen. The most general view we got at Ormeim was that of Vermo Fos itself from above the inn, taking in a part of the terrace at the end of the houses; this made a very effective picture.

After exhausting this place as far as our time would permit, we drove a few miles further to the Sletta Fos. This Fall we found even more imposing than the Vermo Fos. Far away, high up, it sweeps over the rocks, and, in full volume, white and seething, it descends into a chasm hundreds of feet deep, nothing impeding its progress until, down in the depths, it is heard lashing in fury at the bottom. Standing on the frail bridge that crosses the top of the fall and looking over, the very immensity of the body of water lashing on makes one giddy and queer to look down upon it. We clambered away down as far as we could get with safety, and from a point of vantage got two or three good negatives of the Fall.

It was at Ormeim that we first met Sheldon and Thompson, two American gentlemen who were out doing the tour. After this meeting we came upon them here and there, all over the place, as we journeyed along, and we had some good times with them. They were travelling with Bennet's tickets and conveyances. Bennet holds much the same position in Norway as Cook does in England. The advantage gained by having a carriage from him is that you take it with you all the journey instead of having to change at every station, hence your baggage need never be removed, and only the horse and boy are new. This style of travelling comes to be very expensive however, as many of the longest runs are made by water, and the carriage must go with you, and you have carriage to pay for it from place to place, when on board steamer, which runs away with a lot of money for a supposed luxury that could easily be dispensed with, as a carriage can always be at had any station, and when you have run your distance you are done with it, and no bother or responsibility in the matter, so I would advise any one travelling in Norway to hire the conveyances supplied at the stations as a much cheaper mode of travelling, and one attended with less trouble and inconvenience.

The boy we had with us here was a very useful and obliging fellow; we utilised him for balancing many of our pictures. He was quick to pick up an idea and act upon it, and we found him no end of help. He told me one peculiarity regarding names here that struck me as strange. His name was Peter Oaak, the latter being the name of the place where he was born. He said it was quite a common thing in Norway to surname a child after the village or place where it was born, and we really came across many instances favouring this assertion, such as "Bergen," "Naes," &c.

We, on our return journey through the Dal, got into Fladmark on the Sunday. The most we did here till the Monday morning was to "loaf" round and see what was to be seen. One sight we got that is not usual at home, that was an eagle wheeling over the mountain brow, and lingering around a considerable time as if enjoying the Sunday quiet. It must have been a very large bird for it could be seen by the naked eye thousands of feet up, and with Jack's telescope it was perfectly plain.

A little fellow who had heard, away in the hills where he stayed, that

two strangers were passing the night at Fladmark, came all the way from his home, which must have been several miles, with a small stock of white wood carved things tied up in a red cotton pocket handkerchief. He undid the parcel, and, in a sheepish way, placed his wares before us and asked us to buy. The class of articles introduced were wooden salad spoons and forks, knives with white wood carved handles along with some other primitive-looking articles, of which the carving is the principal feature. This carving is done by the inhabitants of these wilds and sold to the tourist and the stranger when passing through. We bought a few pieces from the lad, and he went away home quite happy.

The natural politeness and extreme simplicity of the people are very striking, and often amusing. When you please them with any little act of kindness or courtesy they immediately put out their hands to shake hands with you. It was great fun to sit and watch Jack and the native boys and girls. He carried about with him always bags of sweets, which he was continually giving away to the youngsters he met, so that if there were any about he usually had a small crowd around him; to watch these children when they received the sweets was as good as a play. Out went the sweets from the right hand into the left, and the hand of the giver is grasped, the boys pulling off their caps and the girls so modestly curtsying low. When paying your bill, if you give a small tip, like demonstrations take place, and when your carriage boy has received some sixpence or eightpence for himself, after having driven you some twenty miles, he is quite profuse in his demonstrations of pleasure. Wherever pleasure is conveyed to any one, no matter how lowly in station, out comes the hand to be shaken as a mark of appreciation of your great goodness.

We heard the notes of a bugle, and the echoing sounds came leaping from hill to hill. On making inquiry regarding this seeming levity breaking in upon the silence of the Sunday, we were informed that it was the signal that the postman was drawing near, and we had not long to wait before he came into view, and, driving through the gateway, came close up to the station-house. Here, in all haste, the boy took out his horse; another boy with a fresh one was standing waiting, this he yoked at once, and in the space of three or four minutes was ready for the road again, for he used the same carriage, and the mail bags were securely strapped to the back of it. The postman himself looked the perfect picture of a stage brigand. A tall, powerful-looking man, with a long blue, tight-fitting coat, ornamented with two rows of brass buttons; he had a broad leather belt buckled round his waist, into which were fixed two huge pistols quite exposed and ready for use. In his hand he carried the bugle that helped to enliven the way. He stood waiting by the carriage till the horse was changed, then he got into his seat and drove away without exchanging a word with any one.

I do not know why he should wear pistols, and that in such a pronounced position, for they say that there is no such thing as thieves in Norway. Perhaps it is to keep in check any foreign rascals that may be prowling about.

MARK OUTS.

ON ALLOTROPIC MODIFICATIONS OF SILVER.*

B.—INSOLUBLE FORM OF THE FOREGOING.

The solution of the blue product just described is influenced in a remarkable way by the addition of almost any neutral substance. So far I have not found any that do not precipitate it. Not only saline solutions do this, but even a solution of gum arabic.

Neutral salts may precipitate the silver in either a soluble or an insoluble form. Alkaline sulphates, nitrates, and citrates throw down the soluble form; magnesium sulphate, ferrous sulphate, nickel sulphate, potassium bichromate and ferrocyanide, barium nitrate, even silver nitrate and other salts, throw down a perfectly insoluble form. The soluble form constitutes a blue or bluish-black precipitate; the insoluble a purple brown, which by repeated washing, by decantation, or otherwise, continually darkens.

What is very curious is that the insoluble form may be made to return to the soluble condition. Many substances are capable of effecting this change. Sodium borate does so, producing a brown solution; potassium and sodium sulphate produce a yellowish red solution, and ammonium sulphate a red one. None of these solutions have the same blood-red colour as the original solution; the form of silver seems to change with the slightest change of condition.

The solutions used must be extremely dilute, otherwise the silver, though rendered soluble in pure water by them, will not dissolve in the solution itself, a singular complication of effects. So that if a moderately strong solution of one of the above substances is poured over the insoluble silver substance it does not dissolve; but by pouring off the saline solution and replacing it with pure water the substance dissolves readily. The insoluble substance is also readily soluble in ammonia. The solution has a fine red colour, and not the yellowish red of the sodium sulphate solution.

Most neutral salts act in one or other of the ways just described, precipitating the solution of the blue substance A in either the soluble or the insoluble form; the latter soluble in ammonia. But sodium nitrate is an exception; its solution effects an entire change, and renders the substance wholly insoluble, probably reconverting it into normal silver.

Sometimes the substance will spontaneously pass into a soluble form.

* Concluded from page 462.

A specimen, rendered insoluble by precipitation with ferrous sulphate, after much washing began to run through, not only as a suspension, which often happens, but as a solution, clearing itself after a day or two of insoluble portions, and furnishing a rose-red solution. I have kept this solution in a corked vial for eight months, during which time it has remained unchanged.

The general properties of this substance can be much better observed in the thin films obtained by brushing the moist substance over paper than in the lumps. The films thus obtained are bright greenish metallic, and this green evidently results from a mixture of blue and yellow, as in some lights the blue, in others the yellow, is most evident. When these films are examined by light reflected from them at a large incidence with the normal, and a Nicol's prism or an achromatised prism of calc spar is interposed between the film and the eye, it becomes at once apparent that the blue and yellow light are oppositely polarised. The yellow light is polarised in the plane of incidence, the blue light perpendicularly to that plane. All specimens show the yellow light; but the quantity of blue light is very variable, and is directly connected with the amount of washing applied to the precipitate. The more it is washed, the more the yellow predominates. To see the blue form in its full beauty, a little of the red solution may be precipitated with a very little magnesium or aluminic sulphate, and be thrown on a filter. As soon as the liquid has drained off, and without any washing, the deep bronze-coloured substance is to be brushed over paper. On drying, it has all the appearance of a bright blue metal with a remarkable lustre. The mirrors obtained by brushing the substance over glass are so beautiful and so perfect that it seems as if this property might have useful applications, especially for silvering irregular surfaces. Much care, however, would be necessary in the preparation to obtain a permanent product.

Crystallisation.—On one occasion this substance was obtained in a crystalline form. Some crude red solution had been set aside in a corked vial. Some weeks after, it was noticed that the solution had become decolourised with a crystalline deposit at the bottom. The bottle was carefully broken; the deposit, examined by a lens, consisted of short black needles and thin prisms. Evidently the saline matters present had balanced the silver in solution so nearly as not to cause an immediate precipitation, but a very gradual one only. The mother liquor was drained off, and a few drops of pure water were added. No solution took place; the crystals were, therefore, of the material B, the insoluble form. The contact of pure water instantly destroyed the crystallisation, and the substance dried with a bright green metallic lustre. Contact with pure water evidently tends always to bring this form of silver into the colloidal state, sometimes soluble and sometimes not; whilst the contact with certain neutral salts renders it crystalline.

The extraordinary sensitiveness which allotropic silver shows to external influences contrasts strongly with the inertness of normal (probably polymeric) metallic silver. When we place this fact alongside of the well-known sensitiveness of many silver compounds to light, heat, and (as I have elsewhere shown) to mechanical force, we are led to ask whether silver may not exist in this form in these very sensitive compounds.

To obtain the substance in a pure condition suitable for analysis, it is necessary to choose a precipitant not giving an insoluble product with either citric or sulphuric acid. Magnesium sulphate or nickel sulphate answers well; I have generally used the first named. A very dilute solution is made of it, and the red solution of A is to be filtered into it. The precipitate soon subsides. A large quantity of water is to be poured on, and then washing by decantation can be continued to three decantations, after which the substance remains suspended. It can be made to subside by adding a very small quantity of magnesium sulphate; one-fourth thousandth (0.25 grammes to one litre) is sufficient. The substance may then be thrown on a filter and washed with pure water.

Analysis.—A specimen dried in vacuo over sulphuric acid gave:—

No. 1.....	97.17 per cent. silver.
No. 2.....	97.10 " "

A specimen dried first in vacuo, and then at 100° C., lost in the second drying .83 per cent. water.

So that the substance dried at 100° contained 97.96 per cent. of silver. The remaining 2.04 per cent. consisted of ferric oxide and citric acid.

C.—GOLD-YELLOW AND COPPER-COLOURED SILVER.

It has long been known that golden-yellow specks would occasionally show themselves in silver solutions, but could not be obtained at will, and the quantity thus appearing was infinitesimal. Probably this phenomenon has often led to a supposition that silver might be transmuted into gold* This yellow product, however, is only an allotropic form of silver; but it has all the colour and brilliancy of gold, a fact which was apparent even in the minute specks hitherto obtained.

By the means presently to be described, silver can be converted wholly

* I have a little volume, published in Paris in 1857, by a chemist named Tiffereau, who was firmly convinced that in many reactions minute portions of silver are converted into gold, especially with the aid of powerful sunlight. In Mexico, he affirmed, he had actually produced several grammes of gold, a portion of which he presented to the French Academy with one of his papers. To his great disappointment he did not succeed in repeating these experiments in Paris with more than an infinitesimal result. All gold, in his opinion, had been originally silver; and this belief, he affirms, is universal amongst Mexican miners. The book has for a title, *Les Métaux sont des Corps composés*.

inso this form. It is a little curious that its permanency seems to depend entirely on details in the mode of formation. I have found many ways of obtaining it, but in a few months the specimens preserved changed spontaneously into normal silver. This happened even in closed tubes. The normal silver produced in this way is exquisitely beautiful. It has a pure and perfect white colour like the finest frosted jeweller's silver, almost in fact exceeding the jeweller's finest products. I found, however, one process by which a quite permanent result would be obtained. Specimens made by it in November of 1886 are now, at the end of thirty months, unchanged.

In forming the blue product which I have called A, very concentrated solutions were necessary. C on the contrary is best obtained from very dilute ones. The following proportions give good results:—

Two mixtures are to be prepared. No. 1, containing 200 c.c. of a 10 per cent. solution of silver nitrate, 200 c.c. of a 20 per cent. solution of Rochelle salt, and 800 c.c. of distilled water.

No. 2, containing 107 c.c. of a 30 per cent. solution of ferrous sulphate, 200 c.c. of a 20 per cent. solution of Rochelle salt, and 800 c.c. of distilled water.

The second solution (which must be mixed immediately before using only) is poured into the first with constant stirring. A powder, at first glittering red, then changing to black, falls, which on the filter has a beautiful bronze appearance. After washing, it should be removed whilst in a pasty condition, and spread over watch glasses or flat glass basins, and allowed to dry spontaneously. It will be seen that this is a reduction of silver tartrate by ferrous tartrate. The metallic silver formed by reduction with ferrous citrate and ferrous tartrate is in an allotropic condition; with ferrous oxalate this result does not seem to be produced.

Although the gold-coloured silver (into which the nitrate used is wholly converted) is very permanent when dry, it is less so when wet. In washing, the filter must be kept always full of water; this is essential. It dries into lumps exactly resembling metallic gold, especially the surfaces that have dried in contact with glass or porcelain. For this substance has in a high degree the property already described in forms A and B—that of drying with the particles in optical contact. When the thick pasty substance is extended over glazed paper, it dries with the splendid lustre of gold leaf, with this essential difference, that these allotropic forms of silver, B and C, assume spontaneously in drying the high degree of brilliancy which other metallic surfaces acquire by elaborate polishing and burnishing. By brushing a thick paste of this substance evenly on clean glass, beautiful gold-coloured mirrors are obtained; the film appears to be entirely continuous and the mirror is very perfect.

By continued washing the precipitate changes somewhat, so that in drying it takes on a coppery rather than a golden colour, and is rather less lustrous, though still bright and permanent.

Two silver determinations by conversion into chloride made in November, 1886, gave:—

No. 1	97.81 per cent. silver.
No. 2	97.86 " "

Recently these experiments have been repeated, and the washing was more successful. Ferric tartrate adheres very obstinately, and after a time washing with water ceases to remove it. Stronger means cannot be employed without affecting the substance itself. These last determinations gave:—

No. 1	98.750 per cent. silver.
No. 2	98.749 " "

The residue of No. 2 was examined, and consisted almost wholly of ferric citrate. M. CARRY LEA.

[NOTE.—The editor has received, from the author of the above paper, samples of the three allotropic forms of silver which he describes, and also strips of glass and paper coated with them. Mr. Lea is to be congratulated on his very important results. The coated strips, including the gold-coloured mirror made with the "gold-silver," answer fully to his description. The mirror is remarkable for its perfection and beauty.]

THROUGH JAPAN WITH A CAMERA.

CHAPTER VI.—THE START FROM AWAMORI.—JINRIKISHA TRAVELLING—JAPANESE FOOD.

FROM AWAMORI we started on our inland travels. There lay before us some six or seven hundred miles of road, all to be traversed in jinrikisha, or hand carriage. The following is the history of the jinrikisha, as I have been told it. Before foreigners were admitted into this country, some thirty years ago, the Japanese had only two modes of travelling. One was by bullock carts—a slow and tedious mode, of course—the other was by chairs or baskets suspended between two poles carried on the shoulders of two men—a method still practised when the roads are very steep. It is said that one of the earlier English settlers in Japan brought out a small carriage or phaeton with him, and that the jinrikisha is simply a copy of that on a small scale. Be that as it may, the jinrikisha or kuruma is a thing of but recent date in Japan. Its use must have spread, however, with remarkable rapidity, for it is now to be found in immense numbers all over the country.

On good roads a jinrikisha man will keep up a rate of seven or even eight miles an hour for several hours. When the roads are bad, or when a great distance is to be run, it is customary to have two men, one of whom pulls with a cord in front. In the large towns the hire of a jinrikisha with one man is 10 sen an hour (about 4d.), but from foreigners about double as much is generally expected. Not more than 1 yen (3s. 2d.) is, however, the maximum for one day, and the hire of a jinrikisha and man by the week is only 2 yen, 80 sen (about 8s. 6d.) In the main roads in the country the rate is generally according to distance, being something like a halfpenny per mile for one man, and a penny per mile when there are two.

Jinrikisha riding in the towns, or wherever the roads are good, is a very comfortable and even luxurious mode of travelling, the wheels of the vehicles being large, and the bodies of the carriages being well balanced on easy springs, but I now experienced for the first time travelling on rough and rugged roads. The roads in Japan vary from many as good as the best we have at home to mere stony paths of the very roughest nature. In the case of very many of them, the water, which has to be taken from the higher to the lower side of the road, in place of being carried in a culvert at some distance below the surface, is carried in a ditch covered with a board. This board is intended to be, and doubtless is at first, flush with the road; but very soon the wheels of the vehicles wear a deep groove at each side of it, and one goes flying over these boards with a preliminary and a final bump that is quite surprising. In travelling we did from forty to ninety miles a day, according to the condition of the roads and the number of hours that we gave to steady going. We changed jinrikisha generally at the end of every ten to twenty miles.

The three days after we left Awamori were spent in steady travelling over roads which were not particularly interesting. The heat had by this time become intense. Although we were in the northern portions of Japan, we just happened to strike what was at that time the hottest part. The thermometer rose to 95° or 96° in the shade every day, and there beat down a fierce sun that scorched and blistered the skin. I wore nothing but a white shirt and trousers. One day I opened the front of the shirt; there was a slight breeze, and I thought to get some relief. I certainly did not keep it open for five minutes, yet now, six weeks afterwards, I have a great dark streak down my breast where the sun burned the skin.

We were now fairly launched in the interior. I saw only one foreigner for a fortnight, and there was nothing but Japanese food to be had. I had been warned by all my foreign friends that I must carry English food (potted meat, &c.) with me or I should starve. Although I was told dismal tales of those who had entered the interior, depending on Japanese food only, and how they had returned after a week or two quite broken down, I determined in spite of this that I would not carry any foreign food whatever with me. There appeared to be a want of adaptability in so doing, and I felt sure that when any people ate and lived on any kind of food whatever—except, perhaps, roast missionary—I could manage to exist. I must say I felt a little nervous, however, just before leaving Hakodate. I made the acquaintance there of one of the twelve foreign residents, and amongst other things asked him how long he had ever lived on Japanese food. He smiled very grimly, and answered, "I once starved on it for ten days, but never again!"

The truth is, that most kinds of Japanese food was not to the taste of Europeans, and that, moreover, as it is almost exclusively vegetable, and at that of but a slightly nourishing nature, it is necessary to eat very largely, otherwise one is hungry again an hour or so after a meal. The following is a description of an ordinary Japanese meal, such as one gets at an average Japanese inn:—

The food is brought in on a small square tray, such as I described as used in the case of the entertainment given to us at Awamori. On this there are, as a rule, four bowls with lids and one without. Of the four bowls which have lids (sancers inverted over them) three are generally of wood lacquered, the fourth is of china. These are all fairly large, and stand in the four corners of the tray. The fifth stands in the middle. In it there are generally some slices of raw daikon. This is a vegetable looking like an immensely long white radish, sometimes as much as three or four feet long. It has a strong, rank smell, and a taste which is to me positively disgusting. Most Japanese are very fond of it, and even some foreigners can take it. In two of the larger dishes there is generally soup, in the third often fish or some vegetable compound which I am unable to describe. Meat, apparently, is never used. The china bowl is empty. It is for the rice which is to form the staple part of the meal. The rice is contained in a long wooden vessel with a lid, and is helped into the china bowl as it is wanted.

If one can manage rice in large quantities it is all right. If one cannot, he will fare very badly. For the first few days I could not manage the rice at all. It would be absurd to say, of a people whose staple food is rice, that they do not know how to cook it; but they do not cook it to suit the taste of Europeans. As it is eaten it is a clammy, agglomerated mass, generally tepid, without salt or any other flavouring. A Japanese generally finishes a meal with four or five bowls of this stuff. It simply would not go down my throat at all, and for several days I lived almost entirely on hard-boiled eggs and very sour, hard, unripe apples.

Japan, by the way, is a miserable fruit country. After a few days I got into the way of managing the rice. I observed that some of the people put tea amongst it, and I found that by making it into a sort of "hog's wash" in this manner I could get through a good deal of it; but

I soon found out a still better plan. The rice, as I have said, is not good (to my taste) alone. The soup is palatable enough, but is of the very thinnest nature; a few bits of vegetable or seaweed floating in warm water which has a slight flavour of them, but has never been near meat of any kind. But the rice, however, and the soup mixed made an excellent dish, especially when pepper and salt were available. Pepper, however, was seldom to be got, salt by no means always. The Japanese scarcely use salt at all, and often what was offered to me was so black and dirty-looking that I rather did without it than use it.

I think there can be no doubt that in very hot weather a thin vegetable diet, such as I have described, is better for the health than the heavy meals that foreigners generally eat in the East. It agreed with me most admirably. I got to like it exceedingly after a time, and were I to do the same trip again, would carry nothing with me but pepper and salt.

The meal that I have described may be taken as a typical one. At large towns it was generally rather more elaborate, there being several additional dishes.

Sometimes the people, out of consideration for me, prepared what they imagined to be foreign food, and then verily must I have astonished my internal economy by the mixtures that I poured down my throat. At one place meat was produced. I could not tell of what animal it was, but it was unmistakably meat, and as I had tasted none for ten days, I confess to having fallen to with great avidity, when the first mouthful revealed the fact that the food had been cooked with sugar. It had not received a little flavouring of sugar, but had been saturated with it.

W. K. BURTON.

EARLY DAYS OF AMATEUR PHOTOGRAPHY.

[A Communication to the Society of Amateur Photographers of New York.]

IN speaking about amateur photographers in the early days of this art-science, it would be a convenient thing if I could give you a generally accepted definition of the words "amateur photographer." In the use of the word amateur to-night I shall mean a person who works in or experiments in photography from other reasons than the pecuniary benefit which it will be to him.

On August 10, 1839, the secrets of Daguerre and Niepce were given to the world through the French Government, who, through the influence of Arago, had purchased the secrets at the price of a life-pension of six thousand francs a year to Daguerre, and four thousand francs to Niepce. In less than a year from the above-mentioned date Paris was swarming with amateur photographers. At the windows and on the balconies of the houses could be seen the little instruments adjusted with the sensitive plate waiting for the light to impress an image of some favourite object in its silent and mysterious way.

The city of Paris was thoroughly excited over the wonderful discoveries of their townsman and Niepce. The subject was on every tongue. Friends and neighbours on meeting could talk of nothing else. For a month or two the fever ran riot with business and reason; but in this short time it became an old story; the curiosity and wonder had ceased, because they had become common and familiar; so this first flourishing and prolific crop of amateurs soon passed away, and their silence became as conspicuous as had been their noise.

The fever had subsided without the administration of any drugs. Nature seemed to perfectly understand the excitable character of the French people. In Europe and this country scientists, especially chemists, became deeply interested and studied it from a scientific point of view. Professor John W. Draper, of this city, soon became an expert in making Daguerreotypes, and claims to have been the first person to make a picture of the human face, and that was the face of his wife. The last time I saw it was when Dr. Draper showed it to the members of the American Photographical Society, of which he was President. This was not a Society for amateurs exclusively, but professionals as well. This Society was organized somewhere, I think, in 1858 or 1859. In 1861 Mr. H. T. Anthony organized the "American Photographic Exchange Club." At this time amateur photographers were few, and to be one meant something very different from what it does to-day.

To succeed then meant hard work and study. You were required to know how to make almost everything connected with the production of a photographic print. You must know how to make collodion; how to coat a plate, and how to sensitise and develop it; how to construct the silver bath in which the plate was sensitised; how to make the developer; how to clean the plate; how to prepare the nitrate of silver bath for sensitising the albumen paper; to fume, print, tone, and fix the prints; how to make paste, and how to mount the prints. The amateur of those times was further required to make himself familiar with the chemistry involved in all this work; first, in order that what he did he might do intelligently and successfully, and second, to be qualified to determine with a degree of certainty what was the matter when his chemicals gave unsatisfactory results.

The negative bath was one of his most treacherous friends; he could not predict, with any degree of certainty, what would happen to the next plate by the result on the one immediately preceding it. There seemed to be a demon lurking in the dark room watching for an opportunity to get you into trouble, and, as the negative bath was the most sensitive, he would take advantage of this weak point; and if he had got into it bodily, with all the sulphur and cinders he is supposed to have adhering to his external person, and stirred it

up vigorously with his fabulous pitchfork covered with lava from the pit, it could not have made the bath worse than it would sometimes get in an incredibly short time; and this would always happen at the worst possible moment. If you had invited some *particular friend* to have his picture made—some one to whom you wanted to show what you could do and what beautiful negatives you could make, how expert you had become—then this demon delighted to get into the bath and muddle it, so that, do the best you could, nothing but fog, fog, would be the result. The amateurs of those times wished frequently that Job had lived in their times and had become an amateur photographer; they did not believe he would think a few boils of any account, or if he did he would not have taken the first premium in a competition for patience.

It was such vexatious trials which kept the rank of amateurs thin, and when one happened to be exposed and took the fever he would get over it in a year or two, and so complete would be the cure that you would never suspect that anything had been the matter. There were a few exceptions to this rule, which was when the trouble became chronic. I could point to a few examples of persons so affected; your speaker was one of that class. To him there is a fascination and a satisfaction in experimenting.

The development of an exposed plate brings one into close and intimate relation with nature. You are admitted into one of her interior sanctuaries, while she places in your hand one of her magical wands, and while you look at the white plate before you, lo! a form begins to come forth like a spectre from its winding sheet, and apparently it throws off fold after fold of its snowy environments until it stands revealed in perfection and beauty. What can there be more wonderful than this? With the market supplied with ready-made plates of great variety, so that the most fastidious can be suited, the path of the amateur has become one of comparative ease and pleasantness, and the result has been a great increase in numbers and amateur societies. There is every prospect that this state of things will not only continue, but greatly increase. Photography is one of the three great discoveries of this century—the steam engine, the electric telegraph, and photography.

In looking back through the past centuries, where can there be found three great discoveries so near to each other? There are no five centuries that can show anything like the gigantic strides in discoveries, knowledge, and general advancement of the human family as this one present century. It seems the blossoming time of all the past. These discoveries seem to be the offspring which nature gives us as the fruit of centuries of travail and pain. Copernicus, Galileo, Kepler, and Newton were voices in the wilderness preparing the way for the dawning light of the present time. It is but a prophecy of what will be revealed in the future.

The barriers that heretofore have hindered the car of progress are being forced to give way. We, to-day, are only witnessing the first faint ripples of the incoming tide. If we contrast the present civilisation with the time when men lived in caves and holes of the earth with wild animals, it will be found difficult to realise that the present can be the product of such a past. The way from savagery to civilisation has been a longer and more terrible one than we can well conceive of, with all that has been accomplished by the labour of great minds in the past. Only a fraction of the human family can be called civilised; generations upon generations will come and go, leaving scarcely a sign of advance among the semi-civilised and barbarous.

Progress in the future will no doubt travel with accelerated speed. The light and energy at the disposal of the nations in the lead at the present time are being felt as a potential force in every part of the globe.

HENRY J. NEWTON.

Foreign Notes and News.

"Is the moon inhabited?" is an interesting question that has been proposed times out of number, but with regard to which, nevertheless, nothing precise has been ascertained up to the present time, although modern investigation tends more and more to confirm the assumption that the precious "man in the moon" is the only being who dwells on that dry and barren celestial body. It now appears that the controversy raised by the subject is shortly to be decided to the universal gratification of human curiosity; for the editor of a photographic periodical has been informed, we are told, that a German prince intends having photographic images of the moon taken, and then magnified 100,000 times. Surely such an experiment cannot fail to show any living creatures that may people our satellite! The only suggestion we would make is that timely notice should somehow or other be conveyed to the population of that planet, so that they may be prepared to assume picturesque attitudes for the occasion.

A SHORT time ago a young lady of elegant appearance entered the principal Office of Police in Vienna, and requested an interview with the Commissary on duty. She explained in a troubled manner that her fiancé had disappeared some six weeks ago; he had betaken himself to his native Pest for the purpose of procuring the papers necessary for completing the marriage contract, and since then had not been heard of. She therefore concluded that Herr Joseph Psenek—that was her fiancé's name—had met with an accident. The Commissary promised the lady

to institute inquiries at Pest, and requested her to supply a photograph of the missing gentleman to serve as a guide to the police authorities. A reply was received from Pest which occasioned some surprise to the police of Vienna and perturbation to the young lady. It turned out that the photograph sent was that of a criminal whose real name was Rsooki, and who had long been "wanting" for embezzlements amounting to some 60,000 gulden. The anxiety of the lady thus led to the arrest of her lover, who will probably be shortly compelled to appear before the seat of judgment rather than before the altar of Hymen, as she had fondly imagined.

Our Editorial Table.

DIFFRACTION GRATINGS.

London: Newton & Co., 3 Fleet-street.

DIFFRACTION gratings at popular prices is the keynote struck by Messrs. Newton & Co. One which we have received from this firm containing 2000 lines to the inch, and forms a pretty scientific toy. Unlike those used in spectroscopic observation, and in which the ruled lines are straight, in this one the rulings are circular, as in the once well-known Barton buttons, which were made by placing the flat surface of glass or metal in a turning lathe, the rulings then being effected by a diamond point affixed to an automatically acting slide rest. Mr. Barton, by the way, succeeded in ruling as many as 10,000 lines to the inch.

Accompanying this grating is a little pamphlet giving popular directions concerning the observation of diffraction, and an explanation as to what diffraction means. This pamphlet, price 6d., is lucidly written

SPECIMENS of the Collotype work of Messrs. Bemrose & Sons, Chetwynd-street, Derby, are received. These comprise subjects of varying natures—portraits, drawings, reproduction of wood-carvings, and a panoramic scene suggestive of a view in the Norfolk Broads. All are brilliant and carefully printed.

MESSRS. SAMUEL FRY & Co. are now sending out their Sulphoquinone Developer in bottles containing screwed stoppers. We have received a sample, and consider it a step in the right direction.

RECENT PATENTS.

PATENT COMPLETED.

A NOVEL MEANS OR METHOD OF PREPARING PHOTOGRAPHIC AND OTHER PICTURED CARDS OR MOUNTS FOR CONNECTING THEM IN BOOK-LIKE FORMATION, ALSO IN COVERS FOR THE PRINCE.

No. 15,936. JOSEPH WILLIAM ZAHNEDORF, 14, York-street, Covent Garden.—
June 22, 1889.

THIS invention relates to a novel method of preparing mounts or cards on which photographic and other pictures are printed, pasted, or otherwise secured, so that said cards or mounts may be arranged in a superposed manner, and held by lacing cords passed through holes punctured along one edge of the card or mount and corresponding with holes punctured or eyeletted in side covers, in order to enclose the pictured cards or mounts in superposed order between them, and in such a manner that the compiled series of cards or mounts can be opened for inspection at any part without disturbing their superposed order.

According to the usual method of making up photographic and like mounts into book or album form, the paper of the mount proper is opened or separated along one edge for the reception of a guard or strip of calico or other canvas, or of leather, which when pasted or glued and fixed within the separated portion becomes fixed therein, the flaps of the paper or cardboard being cemented down and made flat. A portion of the canvas is left projecting, and on this a strip of cardboard is pasted corresponding in thickness to that of the mount. This strip of cardboard does not extend to the edge of the canvas, a portion being left in which the back of the leaves are sewn to constitute a book or album for the after application of covers formed of two side boards and a stiff back, so that when the book or album is opened the back part belonging to the side covers remains stiff, the joint being at the edge of the covers only, so that the cover can be folded back and any of the leaves also, so that the mounts appear flat when the album is open.

Now the object of my invention is to attach two strips of cardboard to the guard to form two distinct folding places beyond the inner edge of the mount, and to make one of the strips, namely, the outer one, of greater width than that of the inner one, and to perforate said larger strip so that any number of such prepared mounts can be arranged in a superposed manner to any desired height, the perforations, all of which correspond in the larger strips, serve for a cord or lace to be passed through to hold all the mounts in that superposed condition, the two folding places permitting the compilation of mounts to be open at any part without interfering with the lacing at the back, the series of mounts so laced or kept together constituting a book or album without a positive cover.

In order to preserve the series of mounts as a book, I purpose making covers in exactly the same way as that described with regard to the mounts, the covers

being of sufficient thickness to resist wear and to form top and bottom pieces, through the outer strips the cord or lace is also passed to constitute an outer covering and to preserve the enclosed mounts from dust and dirt, at the same time the side covers are slightly larger to prevent the edges of the mounts from being chafed if the album is set up on edge in a bookcase or on a shelf.

The front edge, the top edge, and the bottom edge of the covers may be secured in any desired manner, such as by tapes or ribbons.

Meetings of Societies.

" 25	Burton-on-Trent	The Institute, Union-street, Mechanics' Hall.
" 25	Halifax Photographic Club	St. George's-crescent North.
" 25	Liverpool Amateur	The Lyceum, Union-st., Oldham.
" 25	Oldham	Masons Hall Tavern, Basinghall-st.
" 25	London and Provincial	

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JULY 11.—Mr. W. Bedford in the chair.

Mr. THOMAS SCOTTON read a paper on *Various Processes for Copying Line Drawings* [see page 476], and accompanied his observations by developing several prints made by the processes in question in view of the members.

At the conclusion of the paper Mr. A. COWAN inquired what means were the best to secure absolute contact between the paper and the tracing when such large sizes as 48×36 were in question. A suggestion had been made in an American publication to wind them round a cylinder which was revolved during the exposure.

Mr. SCOTTON replied that he depended upon good workmanship in the printing frames and the use of plenty of pressure. He used two thicknesses of felt to back up the paper.

With respect to the solution employed for producing extra white lines on the blue ground of a print by the ferroprussiate process, an example of which lino had been produced by the Chairman writing with a pen dipped in the solution, Mr. A. HADDOX said that it probably consisted of oxalate of soda.

In reply to a question as to the keeping properties of the various papers, Mr. SCOTTON said that the Pellet paper would keep indefinitely, the other papers, which were all of commercial manufacture, might be depended on for three months or so.

Mr. J. TRAILL TAYLOR put a question as to whether Mr. Scotton had experimented with toning ferroprussiate prints. Ammonia had been employed but the results were evanescent.

Mr. SCOTTON said that he had toned with gold, but not very successfully.

Mr. HADDOX inquired whether the black process that had been demonstrated was capable of yielding half tones.

Mr. SCOTTON could not say. He observed, also, that sometimes paper that had been kept would not develop satisfactorily with cold water, but did so when the water was heated.

Mr. TAYLOR said that some years since he had experimented with various methods of preparing papers of these kinds. He had a weakness for the oxalate salts rather than the citrates, but had been assured that the oxalates would not keep. It happened, however, that Mr. C. J. Burnett, of Edinburgh, had given him some crystals of the oxalate—ammonio-oxalate of iron—before the year 1864, and in the year 1879 they were still quite good. The late Mr. John Williams, of the firm of Hopkin & Williams, had given him some crystals (which were not commercially produced, and which it was impossible to purchase) in the year 1883 or 1884, and they were quite good now. Another objection that had been made to the oxalates was that there was a difficulty in keeping them when in solution. It was necessary for the bottle containing the solution to be kept in the dark. With regard to solutions that would be injured by contact with air, the bottle should be kept quite full; and to ensure this as the solution was used, pieces of glass might be put into the bottle to keep up the condition of fullness.

A vote of thanks to Mr. Scotton was passed by acclamation.

Mr. Evan Cook was elected a member.

The subject for discussion on the evening of July 25 is *The Preparation of Paper from which Excess of Nitrate of Silver is Removed so as to Confer Keeping Qualities, the Sensitiveness being Restored by Ammonia Fumes whilst Printing*.

BIRKENHEAD PHOTOGRAPHIC ASSOCIATION.

JULY 11.—The President (Mr. Lange) in the chair.

Miss E. Carran, Miss J. M. Huddock, and Mr. J. Petrie were elected members of the Association.

Mr. J. A. FORREST read the quarterly *resumé* of photographic progress, which appeared in our issue last week, and also exhibited several films, carriers, and prints taken on Carbutt's films.

The PRESIDENT gave a brief account of his trip to Norway, and stated that, having run short of plates, he was obliged to use Carbutt's films, but the result on developing was unsatisfactory, the films being full of pinholes and scratches. He advised those who purposed using the films to try them before going away for their holidays.

Several members spoke very favourably of the Carbutt films from their own experiences with them.

Mr. F. Evans exhibited a Wray's casket lens and Rouch's detective camera. Mr. W. B. Beaton (Mr. J. J. Atkinson) exhibited several photographic novelties.

Mr. H. B. Sharpe exhibited an enlarging camera with rack and pinion adjustment for focussing, and an arrangement at the front by which the negative or transparency could be moved into almost any position from the back.

BRIGHTON PHOTOGRAPHIC SOCIETY.

JULY 9.—Mr. W. Jago (Vice-President) in the chair.

Mr. E. J. BEDFORD read a paper on *The Artistic Side of Photography*, which was illustrated by reference to several of the best-known works of Messrs. H. P. Robinson and F. M. Sutcliffe.

On August 13 Mr. J. E. Mayall will read a paper on *A Process of Colour Photography*.

LEICESTER AND LEICESTERSHIRE PHOTOGRAPHIC SOCIETY.

ON Thursday, July 11, thirteen members and friends, favoured by exceptional weather, took an early train for Ashbourne, and from thence by conveyance to Dovedale, the "Peveril of the Peak" Hotel being the end of the drive, where a most enjoyable luncheon was served. Thus fortified, the party, engineered by the President, started for the Dale, where an *embarras de richesses* was soon presented, for delightful scenery—river, rock, and dell—surrounded the party. Mr. Bankart, having been before, led the way to "Pickering Tor" (the Hon. Secretary coming in for his share of pointed remarks in consequence of similarity of name), and, working back to the entrance, found the utility of having a leader acquainted with the district. All the characteristic features of the Dale were secured—"Dove Holes," "Tessington Spires," "Pickering Tor," "Pulpit Rock," and the "Stepping Stones," all claimed attention, and the party were busily engaged until time for returning to the hotel for tea, after which they resumed the drive to Ashbourne, whence embarking, the train soon reached Derby, where being met by the Hon. Secretary of that Society and a few members, a walk through the town and a fraternising chat passed away the time until the train for Leicester, which was reached at a quarter to eleven, all having passed a most enjoyable day.

Fifty-one plates were exposed, with a most excellent average of successful negatives.

Correspondence.

✉ Correspondents should never write on both sides of the paper.

THE STEREOSCOPE.

To the Editor.

SIR,—May I make a few remarks on certain literature and criticism that have arisen from an article signed "F. M. S." in a contemporary of yours—*Photography*? This article treated chiefly of the art side of photography, and, if I read it aright, discussed the stereoscope from an artistic point of view. To this article we had, on May 31, a somewhat strongly worded reply in the columns of *THE BRITISH JOURNAL OF PHOTOGRAPHY*. I was not aware that Mr. Chadwick, the writer of this reply in your column to an article in your contemporary, had any other than a scientific interest in stereoscopic photography; my attention was only called to the fact later. As this literature, and the curious procedure of answering in one paper a leading article in another, caught my attention, and as I have always had an interest in the scientific aspect of binocular vision, I thought I might venture to make a few remarks on the matter as touching the artistic side of photography. I did not see then, any more than I see now, how stereoscopic photography could in any way affect art, and in your contemporary I stated my opinion. I have that article of mine before me, and I assert that throughout it I have kept closely to my record, which was, stereo-photography as artistic. I said distinctly I had "no wish to deery the stereoscope in its own sphere." I appeal to any one who has read without prejudice my article to say whether or not I have described that article correctly.

Next we have Mr. G. R. Baker changing the *venue* once more with evident allusions to my article, but as he knocks down arguments I never set up I need hardly contend with him. We have also the universal provider of information and criticism, calling himself "Junius," putting in his oar, but as I don't know his name, and am consequently ignorant of his authority, I need not trouble myself with his opinions further than to remark that he harps on the "solidity" which no one denies.

Now we come to Mr. Chadwick's brother officer in one of the most admirable photographic societies in the world, as I know from personal observation, and it is a Society, if I mistake not, to which I am personally indebted for kindness which I shall not in a hurry forget. I have all the less hesitation in protesting against such a waste of time by an office-bearer of that Society as was perpetrated by Mr. Abel Heywood, Vice-President, on June 21, as reported in your columns of July 12, Mr. Chadwick being Hon. Secretary of the same Society. Even supposing I had made every statement attributed to me by Mr. Heywood, and supposing the deductions drawn to be mine, still it would have been a sheer waste of time to ridicule without attempting to confute. We all know the effect on some minds of making a quotation and putting a point of exclamation after it, but I fancy the Manchester intellect requires a little more than that, unless it has changed since my last pleasant visit to that city. I see

in your report no sign of an attempt to argue any point I really raised; the whole speech, if correctly reported, must have been simply a tirade of abuse of poor "A. P." In point of vituperation it falls far short of some literature we have lately been treated to in your contemporaries, still it is not bad for a beginner. But comparing Mr. Heywood's oration with what I actually wrote, I can only say I hope for Mr. Heywood's sake the circulation of *Photography* is very small in Manchester. In every case he either makes me say what I did not say, or quotes phrases without their context, or supplies conclusions which I never supplied. I am not going to go into detail on these points, for my time and your space are too valuable. I am willing to present the Manchester Photographic Society with enough copies of this issue of June 13, if I can procure them. I will let the Society judge between Mr. Heywood and me. I will be glad to hear where lies the bluster or abuse of the article, where I said my article was strong, where is the absurdity of a person who does not care for a stereoscope refraining from using one, where I make any statement that can be called a shameful libel. Is it possible that I cannot express an opinion adverse to the stereoscope as an instrument for any particular purpose without uttering a shameful libel, or is this style of literature "catching?"—I am, yours, &c.,

ANDREW PRINGLE.

FILM CARRIERS.

To the Editor.

SIR,—I am surprised that Mr. J. M. Turnbull has thought fit, after his private communication with me, to resort to the correspondence columns of the *JOURNAL* to ventilate a purely private or commercial matter. I am more than surprised when I reflect that he must have known it compels me to make public one or two unpleasant truths that I have already tried to impress upon Mr. Turnbull.

On the 15th of last month Mr. Turnbull wrote to me that he had already patented my film carrier, which was only an infringement of his. I was surprised at this, for not having sent out a single one I could not see how he knew anything about its nature. However, when he closed his letter by quietly asking for particulars of it I began to understand.

In reply, I informed him that having seen his I was able to say that mine was quite a different thing; that if it were ever so similar to his any license I might have to pay would, I thought, have to go rather to the proprietor of the Samuels' sheath, of which his was an imitation, if, indeed, that were a tenable patent, which, as you, Sir, have shown in last number, is a very doubtful question.

On the 20th of June Mr. Turnbull wrote again, but the only material addition to what he had previously said was a statement that Samuels "does not in his patent make any claim for film carriers," and a little gratuitous advice upon patent law, which, like all such cheap material, is scarcely worth the price asked for it.

To this I again replied with a quotation from Mr. Samuels' specification, in which he accurately describes Turnbull's carrier, and I also called his attention to a fact I had forgotten to mention in my previous letter, namely, that, independent of Samuels, or Merritt, or anybody else, his (Turnbull's) carrier was a precise copy of Turner's "Simplissimus" carrier, which had been in the market long before the date of his patent.

If after inquiring into the truth of these statements, and after your own very clear description of the difference between our respective carriers, Mr. Turnbull still persists in calling mine an infringement, it is evidence either of singular obtuseness or of a wilful and deliberate intention to try and deceive the public regardless of truth or accuracy.

I can pardon ignorance of what has never come under Mr. Turnbull's cognisance, but there is no excuse for closing his eyes to palpable facts when brought to his notice. These facts are:—1. That my carrier being a double one, which his is not and cannot be, is not an infringement of his. 2. If it were ever so like his I am not infringing his patent, but simply copying Merritt's lapsed one. 3. Even granting that Samuels had not claimed film carriers, Turner has forestalled Turnbull, and therefore the latter has no patent to make a noise about.

In his second letter to me Mr. Turnbull patronisingly assumes a knowledge of patent law that is admirably exemplified in his dictum that "a perfectly valid patent may be held for an invention that is old if the application of it is new. I have done this" (*sic*) "by patenting the application of metal film carriers for ordinary slides." So I suppose we shall have Mr. Turnbull "coming down" presently upon Eastman, Morgan & Kidd, and, indeed, everybody else who ever made a film carrier, for *infringing his subsequent patent*. I never yet saw a film carrier that was not partly or wholly of metal.

Surely a "little knowledge (?) is a dangerous thing," especially in patent law.—I am, yours, &c.,

W. B. BOLTON.

South Norwood, July 15, 1882.

PHOTOGRAPHING IN THE FRENCH EXHIBITION.

To the Editor.

SIR,—From reading your notice on taking photographs at the Paris Exhibition, I am induced to write you a few lines. I have spent a month there and taken a series of photographs, and enclose the conditions for working there. In 1878 there was no charge or limit of time, so that

subjects could be done at the proper time. Now the hours for working are from eight to twelve or from ten to two, and the price 20.25. What the twenty-five centimes additional was for, except for stamps which were not used, I do not know. The authorities will not grant you a permit to work for the same time at any other hours than those named on the order, which I enclose. The French are noted for their orderly ways; as an instance of this, it is an everyday occurrence in the Exhibition grounds to see 500 people waiting in a line at the entrance to the Eiffel Tower: they move on at the rate of a foot a minute in the most orderly manner and without the slightest impatience.

I mention this to show you that it is innate in the police to obey orders, and they are surprised at others not doing the same. Should one be photographing beyond the specified hours he is politely requested to pack up, and if the order is not obeyed he demands the permit and reports the circumstance, which may end in a refusal to grant another. I was most anxious to take more views after the time named, two o'clock, and in doing so was several times told to move on, which I at once did to another place. I was at last challenged by an inspector, and my order taken from me. I selected the last day for this ruse, so never heard the result.

You speak of free trade: the Commissioners were anxious to make it so, but some enterprising photographers in Paris have created monopolies. They take an attractive exhibit, giving several copies conditionally upon having the sole right.

The "Street in Cairo," a most picturesque subject, I could not do. As soon as I set up the camera I was surrounded by Arabs, and if I tried to be indifferent and persisted on remaining, they had a rope across the street against which they placed planks of wood which spoiled the view. —I am, yours, &c.,

F. YORK.

87, Lancaster-road, Notting Hill, W., July 11, 1889.

P.S. The Photographic Exhibition is now complete, and the display a grand one. Lumière & Sons show excellent work taken all over the world on their films. Nearden's panoramic photographs taken on them are a great success, embracing an angle of 120° free from distortion.

To the Editor.

SIR,—I am sorry for it, but I must ask you to allow me to put things right with Professor E. Stebbing's wrong assertions in regard to the imaginary great troubles experienced by the photographer at the Paris Exhibition.

A party owning a permit for the season cannot take views until eleven p.m., as after two p.m. no more views can be taken; however, it is readily tolerated (Mr. S.'s assertions notwithstanding), as it is well understood that for some objects light is only favourable after two p.m. An infringing of hours for a one day's permit does not entail the loss of outfit. The duty stamp is not twenty-five cents, but twenty-five centimes, or twopence-halfpenny, and the tickets are now sold at fourpence, which does not entail such a large extra expense as Mr. S. seems to want to make it believed. Although the permit is issued for a certain day, it is not lost if not used, as it is readily renewed for any other day.

Having had myself several permits, and having taken views, I can speak of my own experience, which Professor Stebbing seems not able to do, from what he says about the aged photographer, that he only managed to take two views in a four-hours' *séance*. To talk such nonsense when gelatine plates are in use and an exposure of one minute is considered exaggeration is a poor compliment the Professor pays to the readers of your highly interesting and generally truthful and reliable periodical. I have taken lately six good negatives in less than one hour, and not a single policeman asked me for my permit, and I walked all over the Exhibition for that, in full view with my 10 x 12 camera; and never was I asked more than twice for my permit for one day's work. A policeman is assigned to a certain lot or ground to patrol, and one does not interfere with the other, therefore a party has not to run up and down to show his permit, when on a ladder, to every policeman passing. A policeman does not read carefully your permit all through, but only sees the date and hour and tears off one corner, if not done before by another one, to cancel permit. A policeman is almost always very polite and obliging, if you address him politely. However, I never was on a ladder, therefore of easier access; the policeman always kindly waited near me until I was through with that view to look at my permit, having told him I had one.

Nobody should or does ignore that a permit is necessary to take views inside the Exhibition grounds, and the only proof I can say for this is that no foreigner or Frenchman has attempted taking views without permit with a tripod for his camera, and all parties getting into trouble have detective cameras, and with these try to beat the Directors out of a paltry twenty francs, and run the risk for that small amount to commit perjury, saying they did not know. Then why use a detective camera? Taking views with such of moving people is the same on the street as in the Exhibition, and no risk run. To take an interesting view of a building requires focussing and exposure, hence a tripod.

To conclude, I would say that I do not think the present arrangements for taking views inside the Paris Exhibition are perfect, but as they are they are not so very bad, as they allow every one a chance to work there, which certainly should allay some dissatisfaction as compared with former exhibitions here and elsewhere, where only one firm was given the sole right. However, though I am no prophet, I will say this much, that in

the next exhibition held in London the terms will be found less liberal than they are now here. The reason why? Because I think they will find that they made a mistake in giving the right for the season too cheap, and the right for one day too dear. Time will tell. Anyhow, if you consider that with the rapid gelatine plates you can take very well twenty-four negatives in one day of any size, well twenty francs is not too much after all, as it makes about 8d. for each negative.—I am, yours, &c.,

Asnières, July 16, 1889.

E. LISK.

WARM TONES IN WET PLATE LANTERN SLIDES.

To the Editor.

SIR,—I notice, in the "Answers to Correspondents" of the last issue of the JOURNAL, Mr. J. H. Browning, of Victoria, Australia, asks, "Can you tell me how to get any warmer tone on a transparency by the wet collodion and iron development?"

In a paper I had the honour to read before the West London Photographic Society, on the 12th of April last, I described such a method, and as in the very short report sent you of the above meeting the most interesting details were omitted, perhaps, therefore, the following description of my way of working may interest others of your readers besides Mr. J. H. Browning:—

Wet plate transparencies most suitable for toning by the above method are those made with a moderately thin collodion containing a rather large percentage of bromide, or any collodion will do that will give a soft delicate transparency without much contrast.

Such an one after fixing and thoroughly washing is immersed in a bath of iodine and iodide of potassium in water (of a port wine colour) until the whole of the silver image is converted into yellow iodide, which can be ascertained by examining through the back of the glass.

After giving it a good washing under the tap for about five minutes it should be placed in a bath containing hydrosulphuret of ammonia, ten drops to the ounce of water.

The image will now become a rich chocolate-brown in colour right through the film, and it must again have a thorough washing under the tap as before, and if a warmer tone still is required it has only to be placed in another bath containing—

Chloride of gold	1 grain.
Potassium ferricyanide	1 drachm.
Nitrate of uranium	1 "
Water	20 ounces.

The transparency can be left in this until it becomes a bright Indian red, or it can be taken out before it gets so warm in colour, but when taken out it must again have a thorough good washing.

The tone now can be somewhat modified by placing in an ordinary gold or platinum toning bath for a short time.

The success of the above process depends on allowing the action of the different solutions to penetrate clean through the film, and also giving a good washing between each of the operations.

I can only add that the pleasure one feels in making a really good wet plate lantern slide far surpasses anything one can ever feel in working the dry method; in the former case the merit, if any is due, is due to yourself, but in the latter case there is always a questionable amount that should go to the plate maker.—I am, yours, &c.,

Ealing, W.

CHARLES WHITING.

LANDSCAPES WITHOUT FIGURES.

To the Editor.

SIR,—I have read with pleasure a sensible article in *Photography*, by "G. D.," on figures in pure landscapes, or rather on the absence of such. The remarks are much called for at present, for there is a large number of photographers, and the number is increasing, who think that figures in landscapes are a necessary adjunct, and if you show them a view without them you are immediately asked, "But where are your figures?" It would be well for such persons, instead of being guided by the remarks of self-created photographic taskmasters (?), that they should look at the works of painters—of those who have really studied art, and that successfully. If such be done it will be found that a large number of pure landscapes have no figures; and it should be remembered that artists have not only the power to introduce figures into their works, but also of a character suitable to the picture. But how does it fare with the landscape photographer? he has arranged his view, the light is suitable, and perhaps it occurs to him to introduce a figure, but where is a suitable one to be found for the occasion? I am now speaking of England. I am quite aware that a well-known friend of mine is most successful with the old women, who are quite the right sort of folk in the right place, and if they were not older than himself I would have said he trained them from youth for camera purposes. But if you look for a subject from the rising generation—say a country lass—you will not find such, for all now are young ladies, dressed according to the design and shape of the last number of the book of fashion as taken in by the village dressmaker.

I am at present in a delightful Swiss valley, which, however, is about 4000 feet above the sea level. It is surrounded by some of the high Alps, and the valley itself is an agreeable combination of sylvan and rural scenery, with a bright and bubbling stream to give it life. This is the Val d'Iliez, of which its chief village is Champeney, where I am located.

Here, I was informed, that in addition to the scenic attractions of the place I would find many novel figure subjects, and that women were so much to the front in the present female advance to independence that they discarded the skirt and boldly assumed *les pantalons*. But on my arrival I found the villagers dressed in the usual manner, with the exception that some of the women wore red handkerchiefs round their heads, but *les pantalons* were not to be seen. Upon inquiry I learned that in the summer time the women who wore such were so stared at by tourists that they substituted the skirt for the season; but that others, who, like Mr. O'Brien, were determined to stick to their small clothes, retired to mountain chalets to keep company with the chamois, and other such inaccessible animals. As I did not like, under a blazing sun with a camera on my back, to go in pursuit of such game, I gave up the idea of adding such to my figure subjects. But my landlord said to me, "If you do not wish to ascend the mountains we can get one to come down." I at once agreed. The next day the subject arrived, was photographed, received her travelling expenses, and retired. The next morning, when passing round the hotel, upon casually looking into an open window I saw my mountain lass washing up the dishes, and she seemed greatly to enjoy my surprise.

I am afraid I have wandered from my subject, and, speaking for myself, the quiet of sylvan subjects has been to me one of the chief pleasures of our art. There are scenes in nature where it almost amounts to profanity to introduce a human being, for if nature be closely studied it will be found that she has a life of her own; and I quite feel with Byron when he says,—

"I love not man the less, but nature more."

—I am, yours, &c., T. M. BROWNIE.
Hotel de la Dent du Midi, Champenay, July 10, 1889.

Exchange Column.

Will exchange 12x10 triplet by Dallmeyer, with adapters for using the lenses singly, for 7½x5 doublet by Ross or Dallmeyer, or for long-focus rectilinear landscape lens by Dallmeyer.—Address, W. L. c/o Watson & Sons, 313, High Holborn.

Will exchange rolling platform, six feet by three feet, orthoscopic lens by Voigtlander, ten and a half inches focus, and eighteen-inch French view lens, front stops, for printing type and material.—Address, JOHNSON, Photographer, Saxon-street, Dover.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, including queries for "Answers" and "Exchanges," must be addressed to "THE EDITOR," 2, York-street, Covent Garden, London, W.C. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.

PHOTOGRAPHS REGISTERED:—

W. COLES, Watford.—One photograph of the Shah and suite with Prince Albert Victor and Countess Brocklow and party at Ashridge. Two photographs of Prince Albert Victor and party at Ashridge. One photograph of Prince Malcolm Khan and friends at Ashridge.

F. H. WENHAM.—Will note article referred to when published.

STUDIO.—Under the circumstances, you can print on your mounts that you are patronised by Royalty.

M. STAPLETON.—If the prints are "covered with dirt during toning" it is an indication that care has not been taken during this operation. Send a specimen and say what kind of dish you employ in toning and whether it is quite clean.

T. M. W. wishes to know whether caustic potash or caustic soda is the better substitute for ammonia.—Either will answer, but some plates behave better with the one than the other. Unless we knew the particular brand of plate we could not advise.

GEO. LAUGHTON.—You are mistaken as to the abilities of Mr. Alvan Clark, of Boston, U.S.A. His abilities lay not in the direction of the microscope, an instrument for ought we know he never touched, but in the manufacture of high-class astronomical telescopes.

W. H. T. N.—With some of those on your list we are not acquainted; but, from personal experience, we can say you will be perfectly safe and satisfied with C, E, and F. We advise you to confine your requirements to *f*-8, unless in the case of small pictures and portraiture.

B. C. D.—One of the easiest methods of levelling the cameras is to employ a spirit level. There are several different forms of small size now in the market, which may be obtained of all photographic dealers. They are effective and quite inexpensive. Either the T or circular form will answer.

S. TRIGGS.—The spots or, rather, "pits" on the plates forwarded are due to the gelatine. The only plan of avoiding them is to obtain a sample of gelatine which is free from the evil. Procure samples from different sources, and when you find one that suits secure a good quantity of it, as it will not deteriorate by keeping if kept in a dry place.

Q. writes: "Your suggestion to plate makers to mark their plates is a good one, but it would be still better if they were to number them as well. If this were done reference to conditions under which they were taken, as entered in one's note-book, would be easy for all time; now, as soon as they are out of the double back their history is lost."

T. PROTHKROE.—Forms and particulars for the Exhibition of the Photographic Society of Great Britain may be obtained by writing to Mr. E. Cocking, 5A, Pall Mall East, London; for those for the Royal Cornwall Polytechnic Society apply either to the Secretary (see advertisement in present number) or to Mr. William Brooks, Reigate, Surrey.

W. S. ANDERSON.—Our correspondent wishes instructions for making a "graph."—What does he mean by a graph?

ALF. MANSION says he has recently purchased a lens, which he imagines is of foreign manufacture, presumably French, that purports to have the diaphragms marked according to the Photographic Society's standard. So far as he can judge the largest stop, marked *f*-8, is nearly *f*-10.—This is by no means an uncommon thing. We have seen many such examples.

L. M.—1. The difference between the Euryscope and the Rapid of the firm named consists in the former being made of a larger angular aperture, that is to say, with full opening it will work much quicker than the latter.—2. To prevent the mark which comes opposite the hinge of the dark slide, scrape the leather or other hinge and give it a coating of varnish.

W. BILLINGS says he has a very powerful screw copying press, much more powerful than the general type of copying presses, and asks if with such a press it would not be possible to make Woodbury moulds up to the quarter-plate size.—Of course a screw or any other form of press would answer quite as well as the hydraulic, provided the pressure is sufficient. About five tons per square inch is required; hence, for a quarter-plate something over sixty tons is necessary to obtain a satisfactory mould. We have not yet seen a copying press of so great a power.

C. B. JENNINGS send us some of his failures in making bromide enlargements, and complains that he cannot obtain pure whites. He asks if we can suggest a reason. The reason is that the room in which the enlargements were made was not light-tight. It is clear that actinic light was present, and that during exposure, inasmuch as those portions which were shielded by the drawing-pins fixing the paper to the easel, as well as those under the masks, are quite white, while all portions are fogged. The remedy is obvious.

D. MCCLUSKIE asks if the same apparatus as was employed some thirty years ago in the wet collodion process would be available for use at the present time with gelatine plates. The reason for the inquiry is that he has recently been presented with a quantity of somewhat antiquated apparatus, and would like to try his hand at photography, seeing that it is practised by so many of his friends. The apparatus will do quite well for modern photography, but we should advise our correspondent to get one of his friends to overhaul it generally. In former days the plates were not so sensitive as they are now, consequently the same care as now was not taken in making the camera and dark slides absolutely light-tight.

J. CHESTER JERVIS asks "if black Japan varnish (Bates's) on the back of glass negatives is the best means of blocking-out in combination printing, and in the case of the film side requiring blocking-out what is the best medium? I have had no practice hitherto in combination printing, and would be very thankful for a few hints. I have left all your back numbers at my working place in the South of France, so cannot refer. You mentioned at a recent meeting of a photographic society 'that for printing from several negatives one after the other, there was the method of registering printing frames as used by Edwards and by Hemery.' Are there, then, special frames in the market for the work?"—Bates's black is the best medium for blocking-out. It can be used on the face of the negative equally as well as on the back. There are so many systems of combination printing that it would be impossible to give in this column any useful information unless we knew the character or type of negatives to be combined. Regarding the printing frames mentioned, we shall have something to say about them soon.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—5A, Pall Mall East.—Monthly technical meeting, Tuesday next, July 23, at eight p.m.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting of this Club, July 24, 1889, will be on *Copying Engravings*. Saturday outing at Chigwell.

THE London and Provincial Photographic Association have chosen a subject for discussion at their next meeting (July 25) which will prove of great interest and importance to professionals and amateurs alike, viz., *The Preparation of Paper from which Excess of Nitrate of Silver is Removed so as to Confer Keeping Qualities, the Sensitiveness being Restored by Ammonia Fumes whilst Printing*.

LEWES AND SUSSEX PHOTOGRAPHIC EXHIBITION.—There is to be an exhibition as above, from the rules of which we learn that it is open only to the county of Sussex. It is believed to be the first exhibition of the kind held in that part of England. Medals are to be awarded, but no picture which has gained prizes or medals at any other exhibition will be eligible for competition. All photographs for competition must be entirely the personal work of the exhibitor, up to and including mounting. It will open on October 22, and will remain open for that and the two following days. Advice forms and regulations may be obtained on applying to Mr. E. J. Bedford, Hon. Secretary, 10, St. John's-terrace, Lewes.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1525. VOL. XXXVI.—JULY 26, 1889.

THE FRENCH PHOTOGRAPHIC CONGRESS.

As announced some time ago it is intended to hold, in connexion with the Paris Exhibition of 1889, an International Congress of Photography, of which the programme and regulations have reached us, from which we gather the following particulars:—

The members of the Congress will consist of those persons who shall, before the opening of the session or during its progress, pay a subscription fixed at ten francs, in return for which they will receive a ticket admitting to all meetings of the Congress, general or sectional. The said ticket is strictly personal and non-transferable, and confers no right to free admission to the Exhibition.

At the first sitting a Committee will be nominated, with whom will rest the direction of the work of the Congress. It will consist of a President, five Vice-Presidents, of whom two will be foreigners, five Secretaries, of whom two also will be foreigners, and it will be competent to name in addition "Presidents of honour."

The Committee of Direction will arrange the order of the day of each sitting. The work will consist of general and sectional meetings, lectures, and visits to scientific and industrial establishments. The privilege of attending the meetings and the visits arranged by the Committee, of presenting works and of taking part in the discussions, will be confined to members, though delegates from public bodies, French and foreign, will be admitted to the advantages of membership.

The works presented to the Congress in the published programme will be discussed in general meetings, those not entered on the programme will be read at the sectional meetings. No paper can be read, or form the subject of discussion, unless its author shall have communicated a *résumé* to the Committee of Organization at least fifteen days prior to the opening of the session. Several other rules are laid down with regard to the conduct and reporting of the meetings, but they are of minor importance.

The opening meeting will take place on Tuesday, August 6, at 2 p.m., at the Trocadero Palace, and, the closing sitting will be held on Saturday, August 17, at the same time and place. The remaining meetings will take place at the quarters of the *Société Française de Photographie*, 76, Rue des Petits Champs. A lecture on the work of the Congress will be delivered by M. Janssen, director of the Observatory of Meudon, on Tuesday, August 20, at the Trocadero Palace at 2 p.m. The Secretary of the Committee of Organization is M. S. Pector, Rue Lincoln, 9, Paris, to whom all applications for membership should be addressed.

A number of "questions" have been proposed for discussion by the Committee of Organization, and a summary report on

each has been drawn up and printed as a guide or suggestion as to the line to be followed in each discussion, though not in any way limiting the perfectly free treatment of the question. The following brief *résumé* of the various reports may be interesting:—

The first question for discussion is "The Introduction in Photography of a Fixed Unit of Light;" and this is subdivided into subsidiary question (A), "Uniformity in the Estimation of Luminous Intensity in Photographic Operations;" and subsidiary question (B), "Unity in the Method of Determining the Sensitiveness of Photographic Preparations," both of which are dealt with by Colonel Sebert.

In connexion with the first, the reporter (1), after alluding to the photo-metric unit adopted by physicists in accordance with the proposition made by M. Voille at the Electrical Congress of 1881, consisting of the luminous source produced by a surface one centimetre square of incandescent platinum at the moment of solidification, suggests that it will be convenient if the practical standard adopted by photographers correspond with this unit of light. In making the comparison the rays which possess the greatest chemical action are to be taken into account, and the two sources of light compared spectro-photometrically, with special reference to the rays in the neighbourhood of "G" in the blue of the spectrum. It is proposed to confide the research to a special committee continuing the work of the Congress, the choice of standards being subordinated to other practical problems requiring solution, notably the measurement photographically of luminous intensity and the sensitiveness of plates.

(2.) In what concerns the estimation of the sensitiveness of plates, the special committee appointed to study the question have been led to adopt as the measure of sensitiveness the time necessary, after direct exposure to the standard light and development by a fixed plan, to obtain an image of a grey tint forming a normal tone easy to define and reproduce. For gelatino-bromide plates as now used they are led to recommend the employment of a feeble source of light, such as that allowed to pass through a hole one-fifth of a centimetre square in a screen placed in front of an ordinary candle or similar light, the usual precautions being adopted to ensure uniformity. Preferably they recommend a spirit lamp of some kind, a special recommendation being made in favour of the acetate of amyl standard. This form of lamp, indeed, is the one it is suggested should be compared with the Violle standard.

(3.) With regard to the estimation of luminous intensity in photographic operations, it has been decided to renounce those methods based upon the measurement of chemical action upon certain sensitive surfaces by means of special photographic

apparatus, since these, in reality, measure only the functions of the sensitive substance and of the apparatus employed. Nor can it be hoped to value the luminous intensity of the image formed on the ground glass, as this intensity will represent the function of the apparatus employed, and not solely of the real conditions of lighting considered independently of the means used to obtain the photographic reproduction. These methods should be confined to the estimation of the effect to be finally obtained with a given apparatus and under determined conditions. What is required, it is pointed out, is to measure the light emitted by the objects to be photographed themselves, and not the surrounding light; in other words, to determine the brightness of those objects resulting from their mode of illumination, since it is rarely that the photographer has to deal with objects in themselves luminous. After touching on the possibility of introducing coloured screens for the purpose of arriving at correct estimations of colour value, an apparatus similar to the photometer of Mascart is suggested in conjunction with the acetate of amyl standard lamp, either under the precise conditions of Heffner Alteneck, or preferably with a fixed screen provided with a determined opening of, say, one centimetre square.

(4.) Summing up, the two principal points to be held in view by photographers are the employment of the acetate of amyl lamp with fixed screen and aperture, which should be compared as regards its action in the region of the "G" ray with the incandescent platinum standard; and where prisms or lenses are used, the adoption of glass in ordinary use in photographic optics, in order to conform to the everyday conditions of photography as far as possible.

With regard to the second subsidiary question, the determination of the sensitiveness of photographic preparations, the report commences by pointing out the difficulty of obtaining uniform results, owing to variation in the mode of development. The Committee suggest the following general method of procedure. Two or more plates or preparations to be compared are to be treated simultaneously and under identical conditions by exposure to a standard light, in order to produce after development a determined density of tint. The normal tint proposed is the grey tone formed by the mixture in equal parts of black and white, which may be obtained in a simple manner by a series of black hatchings or lines on paper, equidistant, and of a width equal to the white intervals separating them. To facilitate comparison in reading the results it is proposed to employ a scale of tints, consisting of five above and five below the normal, each tint being pierced by an aperture through which the tint to be compared will be visible when the screen is placed in contact with it. The use of a yellow or tinted pellicle is also suggested in order to destroy any differences of colouration.

The plates to be tested are exposed in a suitable frame, in portions, exposure constantly increasing by five seconds to a standard light, consisting of the before-mentioned acetate of amyl lamp, with screen and aperture, the conditions as to area of luminous surface and distance being, of course, constant. The development is, of course, to be always of a uniform character, the ordinary ferrous oxalate being recommended, though for special plates or preparations it may be needful to adopt special measures.

The final estimation is made in the ordinary manner of comparing the developed result with the graduated screen.

The second question for discussion is "Uniformity in the method of measuring the focal length of lenses," and this is reported upon by M. Adolphe Martin. After a lengthy disser-

tation on the rules underlying the calculation of the focal lengths of lenses, single and compound, and the methods in vogue for measuring them, the report sums up by recommending two methods for discussion. 1st. After focussing upon a distant object the position of the screen is carefully marked; then an object of known dimensions is similarly focussed, and the altered position of the focussing screen having been marked, an image of the object is photographed. As many times as the size of the image so obtained is contained in the actual measurement of the object, so many times will the displacement necessary between the two focussing adjustments be contained in the focal length sought for. 2nd. The second method is that proposed by M. Moessard. Fix the objective on a support capable of revolving on a vertical axis, and having focussed on a distant object, move the lens—with regard to the vertical axis—until on revolving it the image remains stationary on the screen. The point of rotation will then be the optical centre of the lens, and its focal length is obtained by measuring accurately from that point to the focussing screen.

The third question, "Uniformity in the indication of the photometric effect of the diaphragms of the lens," is reported on by M. Cornu, who fixes the "unit of photometric power," or "normal photometric power," as equivalent to "the admission by an aperture equal to one-tenth of the principal focal length during one unit of time." There is nothing new in the "conclusions" of the report, all that remains for discussion being apparently the adoption of $f/10$ as the unit and the scale of numbering the diaphragms.

(To be continued.)

ECONOMY IN THE PRINTING ROOM.

RESIDUES (*Sulphides*).

THOUGH the time is long gone by when the photographer, amateur or professional, who, instead of throwing his print washings down the sink, precipitated and collected the silver they contained, was looked upon as a marvellous genius, the fact remains that a large amount of waste occurs in a vast number of otherwise well-conducted studios, and in a few brief articles we propose again to draw attention to this waste and the best way of guarding against it.

In no part of photographic operations, perhaps, is there so much money actually thrown away as in the case of silver extracted in the fixing solutions. The subject has very often been alluded to, but the result of a number of inquiries recently instituted shows that those who make a trade of reducing silver wastes receive sulphides in very small proportion compared with the quantity of chloride sent, which appears to form the staple residue collected by the majority of photographers. The same fact is discovered when inquiries are made among photographic workers themselves, and no observation is more true than that this ineptitude displays a disregard of economy that is as blameworthy as it is foolish. "Oh, it is so easy to throw in a handful of salt and wait for the precipitate to collect, while there is such a bother with 'hypo,' with its offensive smells and general difficulty of collection." This is the usual kind of reply made when recommendations are given regarding hypo savings. We have been credibly informed that one photographer in a large way of business replied to a chemist who urged him to save hypo residues, "I understand! You want to sel-

some of your chemicals to me, but I am not to be caught." What a lamentable state of ignorance!

It is a fact that when the silver is precipitated by solution of liver of sulphur a very disagreeable odour is bound to be produced; but it should also be remembered that, in the first place, a decided excess is needed for this smell to be produced, and, in addition, that as the presence of excess is quickly shown to the eye by a milky appearance at the surface of the liquid, in the collecting out the nuisance need not be long endured.

As to the actual value of the silver obtainable from old fixing solutions, it is worth quite as much, if not more, than that obtainable from print washings, and as the solution used for fixing negatives can also be poured into the same receptacle a handsome addition to the value of the "waste tub" is easily made. It is quite true that the handling of these residues does entail a little more trouble than is needed with chlorides, but this can be minimised by collecting the hypo solution alone and rejecting the washing water. Perhaps five to seven per cent. of the silver obtainable would be so wasted; but that amount might be disregarded without compunction, unless where work on a very large scale is done. It is quite possible that a supposed addition to the bulk of the solutions to be treated, caused by collecting into the vats the first washing waters from the fixed prints as well as the "fixing" itself, may be largely accountable for the rejection of the whole plan of hypo residue collection, and if it should be so, and our suggestion to save the latter alone serve to produce a larger body of sulphide collectors, this article will not have been written in vain. It is further to be observed that the silver thrown down from solutions used for fixing gold-toned prints contains an appreciable proportion of gold also. We have been afforded an opportunity of seeing some residue credits received by a photographer who produces a large number of prints, and the prices given to him for mixtures of chloride and sulphide have varied from three shillings and eightpence to three shillings and tenpence per ounce, the last note we saw being dated June, 1889, and the silver allowed for at the higher sum named, that is to say, the metal obtained the price of fine silver, which, as is well known, is by no means usually realised by ordinary photographic waste. As to the operation of precipitation, it is just as simple as salting print washings. A quantity of liver of sulphur is purchased, and at once covered over with water to dissolve it and prevent its properties being destroyed by the chemical change produced by exposure to air. This is the foul-smelling liquid, but if kept in a corked bottle no nuisance arises. When the jar or vat is nearly full of hypo solution a little of this sulphide solution is poured in and the whole stirred. A little of the turbid liquid so produced is put into a cup and a drop or two of the sulphide added; if further dispersing of colour is produced an additional supply must be added to the vat and the process repeated. The silver will settle in a day, and the supernatant liquid may then be drawn off. If a large excess of sulphide solution has been employed, the smell of the liquid will be very strong; if a small excess only, no annoyance will be felt. If, however, this smell, owing to personal dislike to it or its proximity to the studio, should be too offensive, the best plan would be to oxidise the excess of sulphide by a little chlorine, most readily obtained from bleaching powder—"chloride of lime" solution.

In conclusion, we feel that the method of saving the silver from old hypo cannot be too strongly recommended, and if

once it is attempted as here described, the plan will be persevered in when it is seen how rich a harvest of valuable residue is obtainable, and at so little expenditure of time and material.

WHEN will the police authorities make full use of photography, or employ it under the best conditions? It is true that portraits of all prisoners are taken, but only in a very rule-of-thumb way, and usually by one of the prison officials, whose practical experience hitherto in *portraiture* seems as if somewhat limited. As a result, these portraits are often such vague or unrecognisable likenesses as sometimes to be misleading, or, if not actually misleading, such as to be of little value as a means of identification after the individual has slightly altered his appearance. If the portraits were taken by a skilled portraitist, as they are in some county prisons, instead of by inexperienced officials and after set rules, they would be of more use as a means of recognition. In the case of the portrait of a "party wanted" being published, the process employed for the production of the prints, or at least the results issued by it, are frequently quite inadequate for the purpose intended.

PHOTOGRAPHY can be made of inestimable value to the police authorities in almost every direction, but then it must be worked on a totally different footing to what it is at present. In the days of wet collodion its scope was somewhat restricted, but now the case is widely different. Though, so far as the police authorities are concerned, it is very much "as you were." Too much red-tapeism and military routine still rule in this department, so far as photography is concerned. We have had detective cameras now for many years. The name "detective" was first suggested by reason of the great utility of such cameras for detective purposes generally. They are employed in almost every direction except that of Scotland-yard.

ON the occasion of the East-end atrocities, last year, we alluded to the great service photography might have rendered had it been employed. Then we suggested that divisional photographers should be appointed in the same manner and on a similar footing to that on which divisional police surgeons now stand. If such appointments were made there is no reason why the photographer should not be on the spot with his apparatus as quickly as the surgeon. At the inquest on the unfortunate victim last week there appeared to be some doubt as to the exact position of the body, and this might eventually be of importance. Had a photograph been secured before anything was disturbed, there would have been no doubt whatever in the matter.

ANALOGIES of the subject of celluloid, which as a basis for photographic results is attracting a considerable amount of attention at the present time, it is matter for surprise that it is not employed for the production of mathematical scales. Every one knows the high cost of a really good engineer's or other scale in ivory, yet when once an accurate negative was taken a series of transparencies could be produced at a very low cost, capable of being attached to ivory, ebony, boxwood, &c., as the case might be, and the production of an intricate and elaborate scale would in practice be no more difficult than a simple open divided scale with the usual eighths, quarters, &c. For calculating scales, slide-rules, &c., it would be equally applicable, and, seeing that the original scale might be made on paper of large size, there is no limit to the accuracy and variety of matter that might be included. As to exactitude the finest details would rival those done by the most accurate dividing machine ever contrived.

CONCERNING "dark flashes," Mr. Whipple believes them to be an appearance due to the prints being taken in oblique light, and to be produced by successive reflection from the reduced silver forming the dark line on the negative and the upper surface of the glass of the negative. Professor Stokes, F.R.S., and Professor Curtis, of Harvard University, arrive independently at one and the same conclusion, viz., that the dark flash shown is really the path of a dead flash, that is, a vanished flash which has left a track of heavy nitrous oxide gas behind it in

the atmosphere impervious to the light of the flashes immediately following, and thus appearing opaque in the picture. Under any explanation a very interesting problem is thus before us.

THE FORTHCOMING CONVENTION.

THOSE manufacturers and dealers who intend availing themselves of the unusually excellent opportunity afforded of exhibiting their productions during the Convention week ought to lose no time in making application for space. Owing to the great number of members who have signified their intention of visiting London on that occasion, it is expected that the meeting will be very numerously attended.

Members who intend to read papers should at once communicate their titles to the Hon. Secretary, and the papers themselves must, in virtue of one of the laws, be in the hands of the Council so far in advance of the meeting as to enable their being got into print before the first day of Convention, which, we again remind our readers, is August 19.

COPYING WOODCUTS FOR THE LANTERN.

AT the meeting of the Photographic Club last week the subject of copying woodcuts in the different illustrated periodicals for lantern purposes was discussed. It was pretty generally conceded that the results are, on the whole, disappointing. As a rule, the slides, when projected on to the screen, appeared totally different from the originals, being both coarser and lacking in force and vigour. It was pointed out, however, that in many instances this was due entirely to the original from which the negative is taken. It goes without saying, that if the woodcut itself be roughly executed the coarseness of the lines will be rendered the more conspicuous according to the degree of amplification. The more general defect, however, is not the coarseness, but the want of force, or solidity in the lines themselves. This is not due so much to anything in the copying of the print as to the lines not being solid or uniform on the paper, but what printers term "rotten."

If an ordinary print, such as those in some of the illustrated papers, be examined by the aid of a magnifier, it will be seen that in many cases the ink on the lines is not uniform but granular, or rotten. This may be due to the block itself, but more often it arises from the printing and the paper. If the same block be printed in a fast machine on common paper, as in the case of some periodicals, the result will be totally different from what it would be if it were carefully printed in a hand press on a fine surface paper. The difference in the two prints would be still more marked if lantern slides were made from them and then thrown upon the screen.

In copying subjects such as those just alluded to, rapid plates should be avoided, as usually, unless great precautions are taken, they render the lines in the negative far from being clear and transparent. This quality is a *sine quâ non* in line subjects. Wet collodion is generally preferred for this work, but some of the slow plates specially prepared for copying purposes yield results which are in no way inferior, and they should always be employed. A MEMBER.

PHOTOGRAPHIC INDUSTRIES.—II.

THE FACTORIES OF THE LONDON STEREOSCOPIC COMPANY, LIMITED.*

CONCERNING work which was being executed during the time of our visit, and of which we made note, the following will afford some idea of the very great orders received. 200,000 handbooks, with collotype portraits of celebrities, for one of the leading advertising firms; another similar number, also with portraits, for a popular religious organization; 150,000 specially designed menu cards, for use at the Paris Exhibition; 100,000 views of a steamer, for distribution at the Exhibition (a first issue by one of the large Steamship Companies), and numbers of smaller orders all in course of preparation by this process. Woodburytype prints in great variety for advertising and publication work. Carbon opals, in sets of 10,000 of a subject, taste-

fully strutted and boxed ready for delivery for the American market, and in other sets for the home market as being issued by well-known advertising firms, were seen in course of preparation. In every corner lay piles of work in progress, all relating to large contracts which extend over months in their execution.

In Woodbury work they can readily finish and deliver 1500 to 2000 cabinets per diem, including mounting, spotting, rolling, and packing.

The staff, besides the manager, sub-manager, and staff of clerks, varies from eighty to one hundred *employés*, according to the season, and a notable feature in the Company's business is the number of old hands to be found in every position of importance. Some of the *employés* have been in the business since it started, rising step by step till they now are managers of their respective departments. Others again can record their twenty-five and thirty years' service in the same employ. The principal members of the Works staff live in the Company's houses adjacent to the works.

We have hitherto spoken only of the factory and its output. We complete this article by giving some account of the Company's two London establishments, viz., those respectively in Cheapside and in Regent-street.

The Stereoscopic Company was founded in 1850 by the late Alderman Nottage, in Oxford-street, where he carried on the business of a photographer and scientific apparatus dealer. He afterwards devoted his sole attention to photography, making a special feature of the well-known stereoscope. The present establishments in Regent-street and Cheapside were afterwards opened to meet the demands of a growing business. The old premises in Cheapside were rebuilt some ten years ago with every adjunct then known suited to the requirements of a photographic business, and are admirably adapted for carrying on the extensive wholesale and publishing business which the Company conduct from their City house, as well as meeting the requirements of their large private portrait connexion and outdoor operative work.

The building consists of a basement, with six floors above and two studios, one specially fitted for photographing trade samples and the preparation of subjects for reproduction by their photo-mechanical processes. This is considered a great boon by many of their City customers, who can personally group and arrange, it may be, a handsome suite of presentation plate, a group of feathers, or a show card of the latest thing out in bonnets. Upon entering, we find the retail sales departments for celebrity portraits, albums, &c., and in another department, amateur photographic apparatus, whilst a handsome show of photographic specimens of every style indicates the portrait department, where the first preliminaries are arranged. The Secretary's office and counting room complete the arrangements here. Special notice must be taken of the department which attends to outdoor photography, the Company having a justly celebrated name for its work in this direction. A staff of operators are constantly at work for their numerous City clients, now securing some interesting "light and air" objects, or the relics of a recent fire; again, taking the new business premises of some firm, or, it may be, a choice series of interiors or trade objects, machinery, &c., too bulky to remove to the special studios.

Ascending from the shop, we find on the first floor the wholesale and shipping publication department, and their new commercial department, each with its separate show room; in the former, stock being kept of all leading celebrity portraits, London and other views, fancy frames, opals, &c., from which orders can be executed, and town and country travellers draw their stock as required. In the commercial department will be found registers showing every process worked by the Company, either for publication or for trade purposes, and the samples being taken from actual orders executed are, naturally, more interesting than if specially prepared for show. A staff of draughtsmen are always at work preparing original designs and suggestions for their clients, a leading feature being the preparation of special photographic novelties for advertisers; numerous samples of large orders of this class which they have executed are to be seen. By the combination of lithography with their special processes an almost endless variety of style in artistic publications is obtainable. Special attention is given to the requirements of country photographers, who often have inquiries they cannot carry out for specialities in process work. The new photographic calendars for the ensuing

* Concluded from page 472.

season are specially worthy of notice. The shipping department for filling indents for photographic apparatus, chemicals, &c., meets with all due attention. The floors above are devoted to handsomely furnished reception, waiting, and pressing rooms. The board rooms and general manager's office, artists' and operatives' rooms, &c., each specially arranged for its specific duty, with an efficient staff in every department. As now arranged all the official work of the Company and all matters of a commercial character or wholesale transactions are conducted from the City house.

At the West-end establishment of 108 and 110, Regent-street, we find a totally different class of business, conducted in keeping with the requirements and tastes of a West-end aristocratic *clientèle*. The present premises, although not specially built for a photographic business, are well adapted for the multifarious requirements of the Company, their show-window being one of the recognised features in this popular thoroughfare, for here is displayed the "very latest" thing out, whether it be the last picture of a Royal Princess and her spouse elect, the popular actress in her latest character, or the last new aspirant for literary fame—all appear in their turn in the ever-changing kaleidoscope of their show window. Beyond stating that we found the premises in splendid working order, we shall not enter upon a detailed description, for we were informed that we should shortly have an opportunity of describing the new premises about to be erected by the Company, which in facilities for conducting business and comforts for their clients would surpass anything hitherto attempted. In order to accommodate their increasing West-end trade, the Company have secured the adjacent corner block, and will immediately proceed to pull it down and erect thereon a handsome building of six floors, fitted with every modern appliance, including American patent elevators to every floor and studio, electric lights for all purposes, and the latest scientific and artistic adjuncts in their studios. We may not at present enter more fully into this projected works, but hope before Christmas to be able to speak from actual inspection of the new premises. The business carried on here, as we have said, is chiefly with the aristocracy and West-end families. It is here that all the portraits of celebrities are taken which the Company publish from time to time, and if their studio walls could speak, some interesting reminiscences might be gained of how this and that "Royalty" behaved, what members of Church and State were most easy to photograph and which were the worst sitters, which celebrated beauty had the most negatives taken and which leading actor or actress looked best in their make-up, and what queer oddities in the way of little men, big men, fat men and lean, have been seen to pose in these studios. To look around their walls is like glancing at contemporary history—the familiar and noted faces of the celebrities of the age are so numerous. We were much interested in the direct life-sized heads which by the aid of a 30×24 camera the Company are making a speciality of. They are truly admirable.

Upon entering the premises one is struck with the range of enormous albums displayed. These are found to be classified. Collections of all the published portraits of celebrities issued by the various photographers. And probably the largest collection of views of any one place ever taken are the Company's London series taken by their own artists. The choicest novelties in photograph frames are there in profusion, from the tiny midget to the largest size used; whilst of albums for the drawing-room table, or presentation wedding gifts, and choice mementoes to tempt the tourist visitor, there is no end. Their private portrait business is on a par with that of their celebrity publication, and of equal importance is the Amateurs' Photographic Department, which from its rapid growth is the cause of their needing extended accommodation.

Commenced a few years ago by their throwing open the secrets of the profession to all who cared to read, and offering free lessons in photography to every inquiring amateur, this branch has grown under the Company's fostering care till it probably excels that of any other high class business in London. By a liberal system of exhibitions, in which prizes both in cash and medals were given by the Company, an enthusiastic interest was aroused, and a constantly increasing connexion formed.

We must on no account forget to mention the Amateur Photographic Department of the Stereoscopic Company, which, since its origin six years ago, has been under the management of Mr. Butler

Humphreys, and which has, we believe, grown year by year until now it is one of the largest depôts in England for supplying every conceivable requirement to amateurs and others. It is quite impossible to give any adequate idea of the variety of photographic cameras, lenses, instantaneous shutters, hand and detective cameras, &c., &c., made and sold by this firm, but even a cursory glance at their two-hundred-page list, noticed a fortnight ago, will at once convey an idea of the immensity of the business. There is not the slightest doubt that much of the popularity of amateur photography is due to the enterprise of the Stereoscopic Company, who have now for several years had a large studio and a suite of comfortable dark rooms specially reserved for amateurs, where they can not only develop their own plates, but can receive very practical instruction in any branch, from the most elementary to the most advanced, which is given by a gentleman retained specially for that purpose. These lessons are, in nearly all cases, free, charges being made only in the case of non-customers. These courses of instruction are, we understand, given by appointment only, and so great has been the demand upon the Company during the present season that would-be learners have, in many cases, had to make appointments weeks in advance.

The Company's well-known trade mark of the "Black Band," which encircles their lenses and dry plates, is now a recognised standard of excellence, although when glancing round the well-stocked cases and shelves we noticed that the Company does not by any means confine themselves to their own products, but keep a large supply of plates, &c., by all makers.

We were particularly struck with some very fine specimens of negatives taken on the new Carbutt films, which were shown us by Mr. Humphreys, who stated that the demand had been so enormous that Mr. Carbutt found it quite impossible to supply them in sufficiently large quantities.

The affairs of the Company are now conducted by a Board of Directors, of which Mr. Howard J. Kennard is Chairman, and Mr. Charles G. Nottage Managing Director. The practical control and working of the Company's three establishments is under the care of the General Manager, Mr. J. Lillie-Mitchell, to whose courtesy we are indebted for conducting us over the works.

PORTRAIT PAINTING AS APPLIED TO PHOTOGRAPHY.

[A Communication to the Birmingham Photographic Society.]

It is with great pleasure I meet you again after the elapse of another year, that I may be able to add my mite towards helping you, if not with photography pure and simple, at any rate with regard to art in connexion with photography. It will be understood by all that the treatment of so large a subject in so small a space of time as this paper must necessarily be, can only be regarded as suggestive. Since promising this paper I have had misgivings, viz., to make it interesting to you and its practicability, for without some previous knowledge of the art of painting I don't really see how you will be able to apply it, but some good may be obtained if I can only make it clear, so as to guide you in recognising good work from bad. Again, this paper which I am about to read to you this evening is devoted entirely to oil painting. Water colour, pastels, black and white, will have to be left for a future occasion.

Now art, i.e., painting, unfortunately with regard to photography has not kept pace in proportion as science has done, and quantity is but a poor substitute for quality. We have had, and are having, quantities of the so-called portraits painted in oils, frame included, for 25s. Now, what are these paintings? Why, no paintings at all. They are only photographs smeared over with a little dirty oil somewhat tinged with a little pink for the cheeks, and a little brown for the hair, and so on; and all this so that the *photographs* may be seen through, because the perpetrator of this vile rubbish is incapable of keeping a portrait if he had to paint it legitimately. Further, when the painting, or rather I should say the so-called painting, is completed, it is framed. Ah! and in such a frame (German gilt), which at the expiration of twelve months it will be no doubt as black as my hat.

Now this one fact alone suffices to show how photographers themselves have degraded their own art. Some photographer may say, We have got to live, and we find a ready sale for these so-called oil paintings. Well, I think the sale would have been just as good, if not much better, had a good enlargement been made carefully finished in black

and white, neatly mounted in a white mount, and finally framed in a plain oak frame with a gilt bevel inside. I feel sure the demand would have been just as great, if not greater, besides which the public taste would have been elevated instead of being debased. And what has resulted from all this? Why, artists standing apart, they have watched with sullen jealousy its progress, and marked with satisfaction its deficiencies in some of the essentials of their art. Meanwhile, scientific men have devoted themselves to simplifying the processes and improving the machinery requisite for the practice of photography. Competitive commerce has contributed its quota in cheapening the materials and apparatus, and fascinated by the facilities thus afforded of securing pictorial representations of anything and everything animate or inanimate, thousands of votaries have given themselves up to the new study with an ardour and enthusiasm which has only been equalled by their utter ignorance of true art or its requirements.

I have somewhat strayed from my subject, but will at once lay before you the principles of harmonious colouring. To produce good results in colouring, it is not simply necessary to possess the technical skill to imitate with some success the colour of the original; but a first requisite in the education of the painter is a knowledge of the value of his colours, of their relations and harmonies, and of their effects in combinations and juxtaposition.

As in music, an utterly inexhaustible world of beauty and delight results from the varied combinations and sequence of seven different notes, so in painting, a source of beauty scarcely more limited results from the combination and arrangement of three primary colours. Again, in painting as in music, the beauty does not consist in any one colour any more than it does in any single note, but in the relation it is made to bear to others.

It is true that the province of the portrait painter is, perhaps, more limited in this respect than that of the painter of works of fancy and imagination, as in the case of historical or classical painting, or that of the landscape painter, whilst the scope of the colourist of photographic pictures is *most limited* of all. Still, without some knowledge of the principles of harmonious colouring, he can scarcely hope to even approximate to the best results. And whilst in portraiture in many points the painter is bound to reproduce as nearly as possible the colours inherent in his model, yet in the choice of colour for draperies, background, &c., more latitude is admissible; and here he will avail himself of such analogies or contrasts of colour as that whilst producing a harmonious whole give value and effect to the colours of the complexion.

Straying from my subject, I leave colour to comment upon character, which should be one of the greatest aims when painting portraiture. Did you visit the Art Gallery when we had exhibiting there that splendid collection of portraits by our great painter, George Fredk. Watts, R.A.? If so, you must have been struck by the individuality of each portrait. What marvellous character! You felt you were standing face to face with the individual himself; you could read in those portraits the lives of the men. Allow me to say that this is portrait painting, portrait painting of the highest order. It is this that Tennyson has so gloriously described in *Lancelot* when he says:—

"As when a painter, poring on a face
Divinely thro' all hindrance, finds the man
Behind it, and so paints him that his face,
The shape and colour of a mind and life
Lives for his children, ever at its best and fullest."

Now my object for speaking upon this subject is the fact that photographers have a propensity for obliterating all character; they want it to look clean and nice, and this must be done at the expense of character if necessary, and in most cases is necessary, and must be sacrificed for the *l. s. d.* Now this should not be, for all of you remember Cromwell's words when about to have his portrait painted. He said, "Paint me as I am, *warts, wrinkles, and all.*" Yes, and that is right, but of course there is the other extreme which care must be taken to avoid, not to exaggerate anything, because if you do, you at once launch out into caricature, for the caricaturist avocation is to exaggerate—for example, a man has a large nose, make it larger; a slight cast in one of his eyes, give him a good wholesome squint, and so with the warts, wrinkles, &c.—you must not make them into wens and furrows, but still they should be there; you have no right to obliterate them. This brings me to the matter of retouching. Now retouching is a very great adjunct to the photographer when legitimately used, but when we see photographs of individuals which have the appearance of having been taken from an inanimate statue of carved yellow soap rather than from the living individual, one regrets that the art of retouching should ever have been known to photographers. "Use and not abuse" is the moral to be here applied.

The source of all colour is light, and a beam of white light is divisible into three separate rays—blue, red, and yellow. These constitute the three primary colours, and by their combinations every possible hue is attainable. White light when decomposed by passing through a prism gives what is called the solar spectrum, which consists of the seven colours seen in the rainbow arranged in the following order:—Violet, indigo, blue, green, yellow, orange, and red, and hence it was at one time supposed that each of these was an elemental colour. Subsequent observation has shown, however, that all but blue, red, and yellow were formed by the overlapping of each other.

These colours in their varied combinations are called hues. These hues when weakened by admixture with white are called tints, and when deepened by admixture with black are called shades. The various gradations of tints and shades of one colour form a scale. The presence in happy proportions of the three primary colours or their combinations in a picture produces harmony. Any two primary colours mixed in certain proportions produce a secondary colour which is complementary to the remaining primary colour; thus the mixture of blue and yellow produces green, which is complimentary to red; the mixture of yellow and red produces orange, which is the complimentary of blue; the mixture of red and blue produces purple, which is the complementary of yellow. These combinations may be carried to an almost unlimited extent with similar results. Thus the combination of any two secondary colours will produce a tertiary, which is complementary to the remaining secondary. For instance, the mixture of orange and green produces citrine, which is complementary to purple; purple and green produce olive, which is complementary to orange; purple and orange produce russet, which is complementary to green; and so on.

This statement of the relations of colour is not arbitrary, nor the result of taste or fancy, but is based on absolute inherent principles. They exist as a physical necessity of the organs of vision, as may be ascertained by a few simple experiments. Who amongst you haven't tested this by trying to obtain the 1000*l.* reward offered by Pears if you can prove this principle to be incorrect by looking at those discs—red, blue, and yellow?

This principle applies to every variety and combination of tint; if a red inclines a little to yellow as in scarlet, then the complementary green will incline a little to blue and become a bluish green. If, on the other hand, the red inclines a little to blue, as in crimson, the complementary will incline a little to yellow and become a yellowish green. These combinations may be so multiplied by gradations so delicate that it is impossible for me to enumerate them. But if any of you would like to test the above statements, I am sure you will find it very interesting and can be carried out at a very moderate cost. Procure then a box of wafers of varied colours and a piece of white cardboard. Place one in the centre of the cardboard, look at it for about half a minute, then transfer the sight to the clear part of the cardboard, when its complementary will appear. If you find it does not, don't rush off to Pears for the 1000*l.*, but take it for granted that you are colour blind. If you do see it—try it on a Sunday afternoon after dinner—you will find nothing so soothing and conducive to a quiet Sunday afternoon's nap. Each pair of colours, consisting of a primary and its complimentary secondary also, presents special contrasts peculiar to themselves. Thus blue is the coldest colour, and is also the most retiring; orange, its complementary, is the warmest colour, and the most advancing. Every combination of colour as it approaches to orange or blue is warm or cold in its effect, and has the appearance of approaching the eye or receding from it.

Yellow is the brightest colour and most allied to light, while its complementary, purple, is the darkest of colours. Red is the most positive and exciting of all colours, whilst its complementary, green, is the most soothing of all colours. Complementary colours in juxtaposition mutually enrich each other, and produce what is called the harmony of contrast. Thus purple and yellow of equal purity and intensity become each brighter from contact with the other, the yellow becoming intensified by the extra yellow rays reflected by the purple, and the purple gaining an accession of richness from the purple rays given out by the yellow. From the same cause neutral tints placed in juxtaposition with full hues appear to be tinged with the complementary colour of such hues. Thus, grey placed in juxtaposition with red will assume the appearance of greenish grey, green being the complementary of red.

Colours not complementary to each other are mutually injured by contact. Thus blue and purple placed together are both injured, the blue becoming greenish from the yellow rays emitted by the purple, and the purple assuming a russet tinge from the orange rays reflected by the blue. Besides the effect produced by contrast of hue, that resulting from contrast of intensity is to be considered. If two tints

of the same colour, but of different degrees of depth or intensity, are placed side by side, the deep tint will appear still deeper, whilst the light tint will appear still lighter, the difference in intensity appearing greatest at the points of contact. I have said before that the laws which regulate harmonious colouring are not dictated by fancy, but are based on inherent and absolute relations.

In conclusion, I will here remark that if you will carefully observe nature, it will afford you many pleasing illustrations of harmonious colouring. A striking illustration of the harmony of analogy is seen in the beautifully blended and graduated colours of the rainbow; and again in almost every landscape, where the blue of the distance blends with the cool greens and greys of the middle distance, and these merge into the warmer greens, yellows, and browns of the foreground; or, again, view another landscape when the sun is setting and is flooding and beautifying the whole scene with its golden light—what are its shadows? Have you ever reflected when beholding them? They are purple. With instances of the harmony of contrast nature teems in every garden, field, and moor, as the damask rose with its yellowish green leaf, the scarlet holly-berry and its deep green foliage; and where is the man who has ever crossed a common who has not seen the almost unvaried mingling of yellow gorse and purple heather?

A proper understanding of these principles which I have briefly indicated will enable the colourist, whilst preserving fidelity to nature in the points absolutely inherent in the model, at the same time to so manage the draperies, background, &c., as to give value to the complexion and produce a perfect and harmonious picture.

G. J. SEUSCHALL.

INSTRUCTIONS FOR TAKING PHOTOGRAPHS OF LIGHTNING.

At the meeting of the Photographic Club, on July 10, I was requested to draw up some instructions for taking photographs of lightning, so that photographers, professional as well as amateur, might, in the event of a thunderstorm, be prepared to obtain some really good photographs.

If the following brief instructions be complied with the photographs of lightning will possess scientific value:—

1. The camera should be focussed during the daytime to some distant object, and a mark made on the camera, so that at night it may quickly be adjusted when a storm is approaching.
2. A rapid rectilinear lens with full aperture should be used.
3. The camera should be directed to the part of the sky where the lightning is most likely to occur.
4. The camera should be firmly screwed to the tripod stand.
5. It may be necessary to tilt the camera slightly, especially if the lightning be mostly in the zenith. If this be done a note should be made of the inclination.
6. A portion of landscape, roof, chimney-pot, &c., should, if possible, be included on the plate. If this cannot be done the top of the plate should be carefully marked before it is removed from the dark slide.
7. The exact time of each flash, the interval in seconds between the lightning and the thunder, and the point of the compass in which the flash appeared should all be carefully recorded.
8. It is desirable that there should be only one flash upon each plate.
9. If circumstances permit, two cameras should be used—one fixed on the tripod stand and the other held in the hand—and two separate photographs obtained of the same flash.
10. It would be very interesting and valuable if two or more photographers could obtain pictures of the same flash from different points of view; by this means it might be possible to determine accurately the distance of the flash, and also its movements in the atmosphere.

The Royal Meteorological Society (30, Great George-street, Westminster) will be glad to receive copies of all photographs of lightning that may be taken; even apparently poor ones often contain useful evidence.

WILLIAM MARRIOTT, F.R.M.S.

COPYING PAINTINGS AND WORKS OF ART.

IV.

SUFFICIENT has been said as to the modes of treating oil pictures which have to be copied, but a few lines may be devoted to the treatment of water-colour work. Much could be said here of the excessive differences in manner and style of the modern school of water-colour artists, and there is no greater test of skill and judgment on the photographers part than that of rendering equally well the works of such men, say, as David Cox or Sam Bough, in landscape, of the deceased artists, or of such living

men as Sir John Gilbert, Burne Jones, or Mac Taggart. Everything about the work of all those true artists is so different the one from the other; not only in the methods of doing their work, but in the entire feeling, which is got in as many different ways as there are men. The very texture of the paper on which they were painted contributes to assist the finished result, and yet we photographic copyists must so attune our efforts to theirs as to produce the most perfect similitude, and show the difference of the work of each artistically.

I recollect copying the original study in black and white on grey paper of the late Sir George Harvey, P.R.S.A., for his famous picture of *The Castaway*. This was done the same size and on similar paper, and printed in carbon. When the proprietor, an artist himself, was shown the original and copy together, he had the greatest difficulty in distinguishing the one from the other. These examples are only stated with the purpose of showing, or trying to explain, that the same quality of negative which would suit, say, one of the delicately washed beauties of David Cox would be utterly valueless for one of Gilbert's or Burne Jones. Each person may make his negative in his own way, but there must be that difference in quality which will distinguish the handling as well as merely represent the subject. With framed drawings they may have to be taken as they are, and, if so, the same rules would apply as in the case of oil pictures; but if the drawings are in folio or loose, then the handiest and best way, where practicable, is to put them into a printing frame larger than the picture to be reproduced, which must be supplied with a clean spot and speckless plate glass, against which the water colour can be pressed quite flat. This mode applies as well to all drawings on paper as it does to photographs and other things of that nature; it at once preserves them from all chance of damage, keeps them quite flat, and renders them much easier to handle. It is probably the next best to getting them into optical contact with glass, a thing which cannot be done with water-colour paintings or drawings. If this method is impracticable, then, if unframed, the next best way is to stretch them on a drawing, or other flat board, with thin laths, through which tacks may be driven without them touching the object which is being copied; this method also helps to keep the drawing flat. Where, however, the picture can be so treated without injury, if it be damped on the back and glued or pasted on the board round the edges only, it will strain as tight and flat as can be desired after it dries. Absolute flatness is a *sine qua non* for perfection in this kind of work; this, however, would be better done by a professional mounter.

A few notes may also be put down as to the lenses beyond what has been said. To show that this is necessary, it need only be mentioned that I was shown the copy of a design the other day, taken by one of our foremost firms, which was excellent in every respect, but that it was not true in the straight lines which bounded it, a defect which the producer did not see until it was pointed out to him, and even then could, with difficulty, be made to understand that with the longest focus portrait lens, which was the character of instrument he used, the production of perfectly straight and square lines was an optical impossibility. That tool, the square, had to be resorted to, in order to prove the truth of the objection, which, of course, it quickly did, and the subject being one necessitating absolutely straight and square lines, it was found necessary to use another—a symmetrical doublet—constructed for such-like purposes. Our tools for copying have no judgment—we must supply that; they can only help us in the purely mechanical part of the work; we must supply all the skill and reasoning powers.

In the case of statuary a totally different rôle must be adopted. Take the case of an object, a figure, say, or a group in marble or bronze. With marble the whole effort must be directed to get such a quiet, subdued tone over the white colour of the material that the most delicate shadow of a shade shall be represented in addition to getting out of it—if it be a portrait, figure, or a bust—that particular view which shall most perfectly display the likeness and character of the personality represented in mimic form, always keeping in view the fact that the marble representation is not like a living figure. In one respect, at least, it cannot assist you, in the choice of the best light and shade, as its animate prototype may do. That is the especial duty of the photo-artist to ascertain, and if it be borne in mind that shadows and shade have the principal part to play in bringing out the character and beauty of the object, the high lights appearing only as points compared with the mass of semi-tones, it will be found that to produce the effect the sculptor wishes to convey is quite as difficult a bit of work as can be attempted. It is, indeed, very similar to the efforts of the engraver, who, by drawing and using a series of lines, or dots, or stipple, or by any of the many ways which they adopt to translate the form and colour of a painting, or other work of art, into a representation of the object in another medium, which shall at the same time be not so much a mere triumph of his skill, but rather a near transcript of the

work of art sought to be represented into another artistic language—that of light and shade apart from colour—and yet conveying the painter's meaning rather than that of the engraver.

It is almost futile to attempt to get this kind of detail or effect on sculpture in the open air; there we must be content with what can be got in the best time of the day to suit the subject, and it will be found, as a general rule, that a quiet, grey day is much better suited for such work than a bright or sunshiny one, the delicate qualities of the work being more easily recorded in the duller light; the bright or sunny light has a strong tendency to produce patchiness, causing the high lights to become too pronounced, while the deficient quality in the shaded portions becomes painfully visible. In the studio all this may be avoided by a careful disposition of that light which is wanted to produce the effect desired, and the exclusion of all the rest which would go to spoil the appearance of the finished copy. The sculptor himself knows this so well that he spares no time or trouble to place his work in his own studio in the most effective position, and in practice the best results which have been attained in this direction have been those taken in the sculptor's own place, with an extemporised or arranged background; but of course this is not always practicable, conditions of space generally interfering with the possibility of the camera seeing as the human eye does.

The darker colour of bronze statuary necessitates a considerably different treatment, photographically, to bring out the effects aimed at by the sculptor, which are rarely so delicate as are those in marble; strength, stability, stateliness, and vigour seem more adapted to be expressed by the sculptor when he chooses to present his ideas represented in this noble metal, combined with a certain feeling of grandeur which marble rarely shows, at least in this country. It may be different in the sunny South, but it is more with work in our own islands that we have to do in these papers. To give, then, the true effect to works of art in bronze, a slight sacrifice of the delicacy insisted on for marble may be accepted for the former, and stronger and more effective lighting may be displayed in the resulting photographic copy. A greater breadth of light and broader and more effective shade tend, with this class of art, to bring out what is attempted to be shown in those more massive and effective works which are modelled for "creation in ever-during bronze," which, when left, as it ought to be, in the natural colour it assumes on exposure to the air, is in its own way a magnificent medium to convey the sculptor's thoughts, ideas, and sense of it—maybe the sublime, or only the beautiful, but, still, his conceptions as nearly as possible with the materials he has to work with, for it is certain that no artist in the true sense of the word was ever yet satisfied with his own production. He always sees something which he could have done to make it nearer his ideal. I said when left in the natural colour; in saying so, it was with no wish to decry the opinion of those having different tastes, but having in view one of the prominent London monuments where the bronze figure is gilded, by which treatment what might have been a noble memento is almost reduced to the level of a piece of showy gingerbread. Compare any of the marble groups or bas-reliefs around the base with the central figure, and there will be seen the difference between true and meretricious taste and art. That, however, has little to do with the copying of them as works of art, but it has something, for while those subsidiary portions of a great national monument can be beautifully reproduced, the main and central figure is hopelessly out in the cold, so far at least as photographic representation is concerned.

In dealing with those productions of the sculptor which are not in the round, as it is technically called, but in slight or fuller relief, from a ground generally named as *bas* and *alto-relievo*, using the Italian phraseology, a considerable difference in treatment is necessary. In the *bas-relievo* we have but a slight, and in the case of some of the finest of such works an extremely slight, rise above the level of the marble slab on which the work has been carved, so delicate in some instances, such as in a head by Donatello, to seem more like a shaded drawing than the labour of the chisel and mallet. To give the true effect to such pieces of refined skill requires almost as great delicacy in the photographic copy as exists in the original, and it is here that a knowledge of the value of shade comes in. Such a work, if treated in the studio as a picture would be, and as it has been shown necessary to do, would be simply destroyed. The only way by which the effect the artist wished to convey can be had is to get the object so placed that the light shall come from behind and from the side; if it is anything like the Donatello head rather from slightly above, so that the image is limned in shade as delicate as the work itself. This may be taken to be the correct method of treating all works in low relief where the human form divine is represented, for with any other it is impossible to catch the drawing of the face or figure. It will be seen at once if a flood of light is let loose on the profile or body of such work that it becomes almost invisible from the want of shadow, and further, in these examples in slight relief, the shade should rather be

accentuated than diminished; this can only be done by careful treatment of the light, as suggested above, and shutting off all that tends to destroy the effect sought to be gained; by so doing a most careful and perfect copy can be had from such works of art, and in no other way.

With works in high relief a different kind of treatment must be adopted, but one which the character of subject will govern to a large extent. The forms exhibited in such cases are more pronounced from their higher relief, and the consequent resulting shadows tell their own tale in a more marked degree. In the studio the arrangement of the lighting becomes a very easy task, the principal care needed being that of securing an absence of spotty high lights, and, in exposure, to see that the lens, so to speak, probes the depth of the deepest shade and records it. Out of the studio, in the open air, the getting of perfect reproductions is often a matter of considerable difficulty. Two of probably the finest pieces of such work by any English artist I had occasion to do, and they can be taken to illustrate the remarks; they are by the late Alfred Gatlley, of Chester, I believe. The slab of marble on which each is carved is about twelve feet by seven; the subjects, "The Song of Miriam" and "The Destruction of Pharaoh and his Host in the Red Sea;" these are situated on a mausoleum or tomb in the open air, and are about a dozen feet from ground to lower edges, and situated about due north and south. To get the proper effect here with the one looking south it was found necessary to take the negatives at about an hour and a half after sunrise, and about the same time before sunset. At any other time the effect of the magnificent carving was almost lost; we might call that arranging the light in nature's studio. On the north side similar precautions were necessary; we shall say nothing of the scaffolding, &c. This is quoted only to show the care necessary in copying works of art.

W. H. DAVIES.

JACK AND I IN NORWAY.

VI.—IN THE ROMSDAL ON TO VESTNAES.

WHEN prowling around Fladmark on the Sunday we came upon some immense ant hills, and it was very interesting to watch them hurrying along in their never ceasing toil. They don't seem to have any Sunday off, or if they have it was not the same as our Sunday, for here they were at it as hard as they could pelt. Jack told me a good story about a friend of his, who, when touring once in Norway, by mistake sat down on one of those ant heaps to eat his lunch. He was not long finding out that he was in rather a hot place, for hundreds of these busybodies scrambled away up the legs of his trousers, and he began to feel so uncomfortable, that he naturally looked round for the cause, when he observed the mistake he had made; then jumping up he stamped along the road to the station (as he was going by rail to Bergen), thinking that a vigorous walk would free him of the pests. He felt rather better as he took his seat in the train—two gentlemen only were in the same compartment with him. By-and-by the legion of imps were adding torment, at last it became so intolerable that after explaining the matter to the gentlemen he asked them to allow him to take off his trousers, to see if he could get rid of the ants by shaking his garment out of the carriage window. Permission was readily granted, when down went the window and out went the trousers, but, alas! when fluttering in the breeze they got caught in the telegraph wires and out of his hands they were torn. Aghast he stood panting without his pants. Although the case was serious, an audible smile from his companions could not be resisted, the situation was so ludicrous. By good luck he had in his traps an ulster which came down close to his heels, with this cover-all he disguised himself until he got to his hotel.

One of the gentlemen playfully remarked that if any of his friends recognised him in his present condition they would certainly think he had been to his *uncle's*, and would never dream for a moment of the *ants*.

They were adding a new part to the inn here at Fladmark. This gave us an opportunity of studying their method of building, which was very interesting. The house proper was all built of wood, and dovetailed together with not a nail used in the structure until they got up as far as the eaves, where nails are used for the overhanging work; in some parts where the wood must be bound together wooden pegs are used. The crevices in the wood are all carefully packed in with dry moss. The foundation of the house, and for half a story above ground, is built of stone, the upper part being left open to hold odd things, much the same as a cellar would be used by us, only it is arched and without any doors, and over this the wooden house is erected.

To make the roof, the bark of trees is first spread all over, they then cover this with soil, and sow seed upon it, so that most of the roofs one sees here are thickly covered with grass. They say that a roof so made keeps the house cool in summer and warm in winter. On many of the older houses we saw fir trees growing, some of them as high as five and six feet. They had evidently sprang from the stray seed that had been blown on to the roofs and left to vegetate there.

We photographed many of these houses as types of the Norwegian homes, a variety of which we found ready to be taken all along the valley.

Stones that the tempest had torn from the face of the mountains o rock and precipitated into the vale a long time ago lie scattered over the flat in thousands. They are of such dimensions that in the distance many of them could be mistaken for good-sized houses. The road in many places twines out and in between these boulders that stand twenty or thirty feet high, wearing green caps of moss and grass, with here and there a fir tree standing up by way of feather. We got some picturesque photographs of these rocks, with a figure or two grouped at the base showing the height by comparison. The Government have utilised many of these rocks to some purpose by using them as telegraph wire supports, so that for miles the wires are fixed from one stone to another, thus dispensing with the use of posts.

The roads in this valley are well kept and fairly flat. When once the authorities cut a road and put it into perfect order, it is then by law left for the farmers in the neighbourhood to keep it in order and repair. All along the way is to be found wooden posts about the height of ordinary milestones, on which is marked the farmer's initials, and the part of the road that has been set aside for his special care.

Waterfalls in the Dal are to be seen every few hundred yards, and that for miles on end, rushing from the top of almost perpendicular mountains three, four, and five thousand feet high. These falls are fed from the snow that lies thickly bedded on the top. So thin in volume are many of these streams of water that they get blown away into prismatic spray during descent, and long before they reach the bottom. The perpetual swish of these falls is heard for miles and miles as we drive along.

Up till now the weather had been beautiful, but on our last day in this, the most romantic of spots, the rain came pelting down, and heavy mists capped the mountains, moving on under the pressure of a strong wind, changing form and tint every minute. We caught some of these effects as they chased along, but the weather was not propitious for anything like well-lighted pictures.

The weather got to be too bad for anything, so we packed up and made straight for Naes through a pelting storm that lasted all the way, but thanks to our waterproofs and rugs it never reached further than our faces; in fact, we felt the spanking through the elements more exhilarating than otherwise.

We had no sooner reached Naes than out came the sun and all was bright again. With the exception of this one day's wind and rain we had uninterrupted fine weather during the remainder of our stay in Norway.

We had promised the landlord of the Bellevue to take a negative of his house on our return; this we did along with one or two other general views of the places from Naes to Vestnaes on our way to Söholt.

The distance by water from Naes to Vestnaes is some twelve or fourteen miles, and we reached the latter at nine o'clock in the evening. Our programme was to cross the hills to Söholt that night, a distance of twenty English miles. On leaving the boat we had a ten minutes' walk up hill to the station-house. We found it rather a better class place in appearance than any of the inns we had yet visited (not including the regular hotel). It looked like a good-sized farm built in the form of a square, with so many doors to it that we were puzzled which was the one intended for tourists. We walked all round investigating, and not a living soul came out to direct or make it more easy for us, and they must have seen us from the windows. We hammered at door after door till we got an answer, and then we found the apartment that was set aside as the public room. On our entrance two young ladies were sitting there (we found this a usual custom), they no sooner saw us than they hurried from the room without saying a word. We were rather astonished at this, for we were usually greeted by the female portion of the household at the stations, and in most cases they had a little English to smooth the way for us. In this case the young ladies were peculiarly English-looking in dress, arrangement of hair, and general appearance, and we thought it strange that in the most civilised house of the class that we had visited we should be treated with the least civility.

But it seems that the keeping of stations and the hiring out of horses and conveyances is a business that the farmers would rather be without, for they are bound to run at fixed rates as arranged by Government, and these rates are very low for the distances to be travelled. The authorities, however, have decided where the stations shall be situated best for the convenience of travellers, and the inhabitants of the district must supply or see that the necessary horses and conveyances are supplied. The *faste*, which means a fixed station, must keep a certain number of horses. When you come to such a station they will at once produce their day-book; by reference to it you will see how many horses are out. If all are away you will have to await the return of one; but there are usually horses at the station, and you get supplied at once. You then enter your name and destination in the book with number of horses, &c., for the information of the next comer.

As no one about seemed to be able to speak English at this place, we arranged by signs, as much as anything else, to get a very comfortable meal in the shape of a meat tea before starting. Then, in the midst of a most unintelligible series of orders and directions to the boy, who did not seem to understand a single word, out came the two young ladies who had disappeared so suddenly on our entrance, and in the most fluent English said that the road we were going was very rough, and that we had better stay till the morning, as it would take the greater part of the night to reach Söholt.

Jack explained that we had to catch up a boat at Söholt on the morrow, and, thanking them for their courtesy, said we were forced to go to-night.

But I could not help thinking that if our young friends had only come forward a little sooner, and had not been so tardy with their English, it would have been easier for us, and it would not have done them much harm.

MARK OUTE.

COMBINATION PRINTING.

FROM time to time we have questions sent to us by our correspondents asking for some method of making a combination print from two or more negatives. As the matter is of some importance, and as the most pleasing artistic effects can oftentimes be produced by such combination printing, it may not be out of place to describe briefly the methods followed and the mistakes that are to be avoided. This class of printing is alike useful to both professional and amateur photographers. A landscape may be taken in which some part of the picture is not agreeable or will not print correctly from lack of ability to focus or otherwise. A fine view of a river, with hills beyond, might be marred from the fact that in obtaining a good focus of the distance the foreground is indistinct, and the printing of it produces nothing but a blurred appearance. Under such circumstances, if two negatives are taken, one of the distance and another of the foreground, they can be combined in printing, and a harmonious picture will be obtained. Again, a pretty landscape may be utilised as a background for a figure portrait or for a group, and some of the most artistic and attractive pictures we have seen have been made by just such combinations.

The beautiful effects of printing into landscape clouds from negatives specially taken for the purpose must have been noted by every one interested in the artistic side of photography. Indeed, a landscape picture without cloud effects is lacking in just that feature that makes such views most attractive to the eye, and these effects cannot often be obtained at the same time that a good negative of the landscape is secured. In such cases double or combination printing is one of the most desirable resources of the photographer. By using a yellow glass screen in front of the lenses the superior actinic effect of the sky can be modified, and clouds that would give over exposure under ordinary circumstances can often be obtained on landscape negatives, but, as a general rule, landscape negatives taken without special precautions give perfectly white skies in the printing. Furthermore, it often happens that when the clouds are particularly beautiful, the light effects of the rest of the landscape are unattractive and commonplace. It is, therefore, almost always best to print clouds into a landscape from specially prepared negatives. But one very important circumstance must be considered in all cases of combination printing: the lighting of the objects in both negatives must be from the same direction. If this is not carefully considered the most inharmonious and startling effects will be produced in the prints from the combined negatives.

The method of making these combination prints varies a little according to the particular combination to be made. When clouds are to be printed into a landscape, the negative of which is cloudless, the first thing to consider is the direction of the light in each negative in the combination. A print of the landscape is now made upon albumen paper, and then carefully cut at the skyline of the print. That portion of the print which covers the landscape section of the negative is now fixed to the cloud negative, the albumen side to the film, and when exactly in position is fastened with mucilage in two places at the lower corners. The portion of the cloud negative left uncovered should be suited to the character of the landscape, and also arranged to produce an artistic effect. In cutting the landscape print to form the mask, care should be taken not to cut into the sky portion. If a little of the landscape part is cut away, when used as a mask, it will allow the cloud negative to overlap the landscape portion in the printing, and this is not easily noticed, but if the landscape section overlaps the skyline the defect is readily noticeable. Having arranged the cloud negative with its mask, make a print, in the ordinary way, from the landscape negative, which gives a white sky in printing. When the necessary details are out in the landscape, remove the print from the negative and place it under the cloud negative, very carefully adjusting the skyline to overlap (just a trifle) the landscape. In printing, shade the horizon a little in order to produce a lighter impression at that point in the print, for it will be noted that this portion of the sky usually appears slightly less dark than the rest.

The principle above described (masking out) can also be applied to the arranging of a figure, or even a group of figures, in a landscape. Taking the case of a single figure, a print is made from the negative containing it, and the figure is carefully cut out with a sharp penknife,

in such a way that both the figure and the surrounding part of the print are carefully preserved and will fit each other. In this way two masks are obtained—the figure, to use with the landscape into which it is to be printed; and the surroundings, to be used to cut out all but the figure in the negative from which it is printed. The figure (with its masked surroundings) is printed first, and then the landscape negative (with its figure mask) is adjusted to make the composition. Great care is necessary to make the masks register neatly, and if there are any defects in this regard they can usually be remedied by re-touching the prints with India ink. By a series of steps similar to the ones we have indicated, three, four, or even six negatives can be used to make combination prints. But, to quote Mr. H. P. Robinson in *Silver Printing*, "A photograph produced by combination printing must be deeply studied in every particular, so that no departure from the truth of nature shall be discovered by the closest scrutiny."

—Anthony's Bulletin.

ON ALLOTROPIC FORMS OF SILVER.

II.

In the first part of this paper were described certain forms of silver; among them a lilac-blue substance, very soluble in water, with a deep red colour. After undergoing purification it was shown to be nearly pure silver. During the purification it seemed to change somewhat, and consequently some uncertainty existed as to whether or not the purified substance was essentially the same as the first product; it seemed possible that the extreme solubility of the product in its first condition might be due to a combination in some way with citric acid, the acid separating during the washing. Many attempts were made to get a decisive indication, and two series of analysis, one a long one, to determine the ratio between the silver and the citric acid present, without obtaining a wholly satisfactory result, inasmuch as even these determinations of mere ratio involved a certain degree of previous purification which might have caused a separation.

This question has since been settled in an extremely simple way, and the fact established that the soluble blue substance contains not a trace of combined citric acid.

The precipitated lilac-blue substance (obtained by reducing silver citrate by ferrous citrate) was thrown on a filter and cleared of mother water as far as possible with a filter pump. Pure water was then poured on in successive portions until more than half the substance was dissolved. The residue, evidently quite unchanged, was of course tolerably free from mother water. It was found that by evaporating it to dryness over a water bath, most of the silver separated out as bright, white, normal silver; by adding water and evaporating a second time, the separation was complete, and water added dissolved no silver. The solution thus obtained was neutral. It must have been acid had any citric acid been combined originally with the silver. This experiment, repeated with every precaution, seems conclusive. The ferrous solution used for reducing the silver citrate had been brought to exact neutrality with sodium hydroxide. After the reduction had been effected, the mother water over the lilac-blue precipitate was neutral or faintly acid.

A corroborating indication is the following:—The portions of the lilac-blue substance which were dissolved on the filter (see above) were received into a dilute solution of magnesium sulphate, which throws down insoluble allotropic silver of the form I have called B (see previous paper). This form has already been shown to be nearly pure silver. The magnesia solution, neutral before use, was also neutral after it had effected the precipitation, indicating that no citric acid had been set free in the precipitation of the silver.

It seems, therefore, clear that the lilac-blue substance contains no combined citric acid. Had the solubility of the silver been due to combination with either acid or alkali, the liquid from which it was separated by digestion at or below 100° C. must have been acid or alkaline; it could not have been neutral.

We have, therefore, this alternative. In the lilac-blue substance we have either pure silver in a soluble form, or else a compound of silver with a perfectly neutral substance generated from citric acid in the reaction which leads to the formation of the lilac-blue substance. If this last should prove the true explanation, then we have to do with a combination of silver of a quite different nature from any silver compounds hitherto known. A neutral substance generated from citric acid must have one or more atoms of hydrogen replaced by silver. This possibility recalls the recent observations of Ballo, who, by acting with a ferrous salt on tartaric acid, obtained a neutral colloid substance having the constitution of arabin, $C_6H_{10}O_5$.

To appreciate the difficulty of arriving at a correct conclusion, it must be remembered that the silver precipitate is obtained saturated with strong solutions of ferric and ferrous citrate, sodium citrate, sulphate, &c. These cannot be removed by washing with pure water, in which the substance itself is very soluble, but must be got rid of by washing with saline solutions, under the influence of which the substance itself slowly but continually changes. Next, the saline solution used for washing must be removed by alcohol. During this treatment the substance, at

first very soluble, gradually loses its solubility, and when ready for analysis has become wholly insoluble. It is impossible at present to say whether it may not have undergone other change: this is a matter as to which I hope to speak more positively later. It is to be remarked, however, that these allotropic forms of silver acquire and lose solubility from very slight causes, as an instance of which may be mentioned the ease with which the insoluble form B recovers its solubility under the influence of sodium sulphate and borate and other salts, as described in the previous parts of this paper.

The two insoluble forms of allotropic silver which I have described as B and C (B, bluish green; C, rich golden colour) show the following curious reaction. A film of B spread on glass and heated in a water stove to 100° C. for a few minutes becomes superficially bright yellow; a similar film of the gold-coloured substance C, treated in the same way, acquires a blue bloom. In both cases it is the surface only that changes.

Sensitiveness to Light.—All these forms of silver are acted upon by light. A and B acquire a brownish tinge by some hours' exposure to sunlight. With C the case is quite different, the colour changes from that of red gold to that of pure yellow gold. The experiment is an interesting one, the exposed portion retains its full metallic brilliancy, giving an additional proof that the colour depends upon molecular arrangement, and this with the allotropic forms of silver is subject to change from almost any influence.

Stability.—These substances vary greatly in stability under influences difficult to appreciate. I have two specimens of the gold-yellow substance C, both made in December, 1886, with the same proportions under the same conditions. One has passed to dazzling white, normal silver, without falling to powder or undergoing disaggregation of any sort, the fragments have retained their shape simply changing to a pure frosted white, remaining apparently as solid as before; the other is unchanged, and still shows its deep yellow colour and golden lustre. Another specimen made within a few months and supposed to be permanent has changed to brown. Complete exclusion of air and light is certainly favourable to permanence.

Physical Condition.—The brittleness of the substances B and C, the facility with which they can be reduced to the finest powder, makes a striking point of difference between allotropic and normal silver. It is probable that normal silver, precipitated in fine powder and set aside moist to dry gradually, may cohere into brittle lumps, but these would be mere aggregations of discontinuous material. With allotropic silver the case is very different, the particles dry in optical contact with each other, the surfaces are brilliant, and the material evidently continuous. That this should be brittle indicates a totally different state of molecular constitution from that of normal silver.

Specific Gravities.—The allotropic forms of silver show a lower specific gravity than that of normal silver.

In determining the specific gravities it was found essential to keep the specific gravity bottle, after placing the material in it, for some hours under the bell of an air pump. Films of air attach themselves obstinately to the surfaces and escape but slowly even in vacuo.

Taken with this precaution, the blue substance B gave specific gravity 9.58, and the yellow substance C, sp. gr. 8.51. The specific gravity of normal silver after melting was found by G. Rose to be 10.5. That of finely-divided silver obtained by precipitation is stated to be 10.62.*

I believe these determinations to be exact for the specimens employed. But the condition of aggregation may not improbably vary somewhat in different specimens. It seems, however, clear that these forms of silver have a lower specific gravity than the normal, and this is what would be expected.

THROUGH JAPAN WITH A CAMERA.

CHAPTER VII.—AKITA, JAPANESE BELLS, A PRIVATE HOUSE.

SEVERAL days of travelling brought us to a town called Akita, where we stayed several days. Akita is a fair sample of a considerable Japanese town, but I don't think I have anything to say of it that would be particularly interesting to readers. For one thing the thermometer still kept going up to 95° in the shade every day, and what energy was left me was all taken up in attending to business. Let me say, however, that the 95° temperature of Akita with dryness was not nearly so oppressive as 85° in Tokio with the dampness that I wrote of at the beginning of these papers.

There is a very fine old castle at Akita, which I might have photographed had the weather been cooler, or had we been less busy, but I am glad I did not, for the castle we afterwards saw at Shirakawa was quite as fine, and much more photographable—of it more hereafter.

I made two exposures towards the evening from the roof of the hotel we stayed at. The bell tower will form an excuse for a few words on Japanese bells. There is at least one of these in every town of considerable size; there are many of them in very large towns. They are often elaborately ornamented with figures, &c., but the great beauty of them is in the sound they give. There is nothing of the metallic clash

* Watts' Dict., original edition, V. p. 227.

about it. At a little distance it comes as a clear, booming musical note of the extremest purity and sweetness. The tone is attributed by many to the fact that the bells being religious institutions, the people mixed gold and silver with the baser metals when they were cast. I do not doubt the existence of a small proportion of gold and silver in the composition of the bells; but I would need some proof to make me believe that the minute percentage likely to be present has any material effect on the sound given out. I cannot help thinking that the shape of the bells, and the fact that they are struck with wood, not metal—the wood consisting of a bank of timber suspended after the manner of a battering ram—has a good deal to do with it. When a bell is struck with a metallic clapper, a deal of noise, produced by the contact of the metals, is sure to accompany the true musical note of the bell.

We left Akita one morning very early, having a long day's drive before us. The road the first day was not particularly interesting, but the second it was very beautiful. We had again a long distance to get over and the making of any exposures was out of the question. Seeing how badly my plates had turned out I am not sorry, but I have a note in my note-book, on the suggestion contained in which I intend to act next summer, if circumstances permit. Here it is.

"We travelled almost the whole day through almost the most lonely valley that I have ever seen. The road is by the side of a deep gorge with a river flowing along its bottom. It is to be noted that it would be well worth while to spend a week between Yokoto and Midzusawa with a large camera; and Nagasaki-san mentions the road between the former of their two places, and Yamagata as still more wonderful, especially at Nozomi."

At the end of our second day's journey from Sendai we arrived at a large village, or small town, which was the birthplace of my travelling companion, Dr. Goto. Here we stopped as guests at the house of a friend of his, and as it is the first and only time that I have stayed in a Japanese private house, I give a short description of it.

Nokote-san, our host, is a merchant, or, as we would say, a shopkeeper. The shop faced the street. There was a passage at the ground level, between the two raised platforms forming the floor of the shop. This passage led to the private part of the house at the back. In the large room the whole family (three generations apparently) lived. The room was capable of being partitioned off by screens, so as to form a number of small rooms, as much separated from each other as Japanese rooms ever are. There was a large square hole in the floor with a fire burning in it, over which all the cooking was done. In the "guests room" we were lodged. Except for the posts supporting the roof, it was in the daytime quite open to the living rooms on one side, and to the courtyard on the other. We were told that when the Mikado had passed through the town he had lodged in the same room, the house being the largest, and the owner of it the richest man in the village. Certainly this room would, in its perfect simplicity of beauty, have put to shame the drawing room of any shopkeeper or even merchant prince at home.

The grandfather of the household was brought in and introduced. He was positively over-powering from his extreme civility and from the number of times that he saluted. His eldest son, the head of the house, also appeared to make his respects. He also was very civil, although not to the embarrassing extent that the old gentleman was. His eldest daughter waited on us, a pretty girl of some sixteen years. She spent the winter months, he told us, at a school in Tokio, where she studied English, amongst other things. She was too shy, however, to speak it with me—a most unusual fault with Japanese girls.

At night our room was closed in on the two open sides by a series of sliding doors or panels.

W. K. BURTON.

Foreign Notes and News.

HERB PAUL BALTIN writes from Potsdam, in reply to numerous inquiries or formulae for permanent concentrated hydroquinone, to recommend the following:—

In 500 c.m. of water, warmed in a flask sufficiently large to allow of convenient shaking, are dissolved—

200 grammes, chemically pure, sodium sulphite, or better,
100 grammes of Kahlbaum's anhydrous sodium sulphite.

After complete solution of the sulphite, 25 grammes of hydroquinone are added and dissolved by shaking.

In a second flask are dissolved 300 grammes of pure carbonate of potash in 300 c.m. of distilled water.

When both solutions have become perfectly clear, they are mixed together and introduced into flasks with patent stoppers, which are so constructed as to prevent any air standing above the fluid. The developer when thus bottled will last for any period of time; but the bottles when once opened must be used up in a week or a fortnight. For actual use this developer must be diluted with five times its volume of water; three to six plates may be "brought out" consecutively in one bath of the solution.

Since the formation of the Photographische Institute for instruction and research in Vienna, such a large number of works have been produced

that it has been determined to hold, at the end of the school year, an Exhibition of all the prints and drawings that have been finished in the Institution. The Exhibition will comprise portraits, landscapes, reproductions, coloured prints, orthochromatic-photography printing, photolithography, &c., together with the work of the pupils in drawing and retouching.

M. BOUILLAND states, in the *Moniteur de la Photographie*, that the method he employs for developing instantaneous plates is as follows:—

Carbonate of soda	250 parts.
Sulphite of soda	60 "
Water	1000 "

Dissolve hot, and then add after filtering—

Hydroquinone	10 parts.
--------------------	-----------

If the time of exposure has been too short, one adds to the ordinary developer 30 to 50 per cent. of a developer composed as follows:—

Carbonate of potash (pure)	500 parts.
Sulphite of soda	60 "
Water	1000 "
Hydroquinone	10 "

If the exposure be very much too short, this latter developer is employed alone. The image appears almost instantaneously. With large doses of the carbonates the degree of sensibility attainable hardly appears to have any limits.

CAPTAIN HINDLY recommends the addition of yellow prussiate of potash (potassium ferrocyanide) to the hydroquinone developer as a means of gaining "depth" in the negative. He advises the addition of a few drops of the prussiate solution (30 parts to 100 of water) to the developing solution. This acts in a similar way to bromide of potassium, but has this advantage, that it does not exercise the restraining action of that compound.

DR. EDER, who has been recently studying zircon, recommends this substance strongly for employment in photo-micrography. The zircon is secured in platinum discs, and is said to improve by use. If any fragments of zircon are broken off, they are pulverised in a mortar and compressed back again into their platinum frame.

DR. EDER has also been experimenting with Brenzcatechine, and gives the following receipt as productive of good results:—

A.	
Brenzcatechine	1 part.
Sodium sulphite	4 parts.
Water	40 "
B.	
Potash	4 parts.
Water	40 "

One volume of A is mixed with two volumes of B. This developer acts much more rapidly than any similarly composed hydroquinone developer, produces as much or rather more sensibility, and the negatives attain the required degree of strength quicker.

ACCORDING to Dr. Carl Arnold, although pyrocatechine is actually many times dearer than hydroquinone, it can nevertheless be employed without increasing the cost of developing, as its action is about fifteen times more powerful than that of the cheaper substance. Dr. Arnold states that to develop a 18×24 plate one-twentieth of a gramme of pyrocatechine with five grammes of carbonate of soda, and a proper quantity of water, is quite sufficient. For travelling he prepares his developer as follows:—To a solution of the alkali of the desired degree of concentration is added a small pinch of pyrocatechine, which is dissolved by shaking. This solution, amongst other of its advantages, may be employed for developing bromide paper and transparencies. Doubtless, when the employment of pyrocatechine has become more general, its price will not be long in coming down.

DR. EDER has recently pointed out the fact, which is perhaps not universally known, that both pyrocatechine and brenzcatechine are compounds isomeric with hydroquinone of the formula $C_6H_6(OH)_2$.

Our Editorial Table.

NEW CATALOGUE.

By MARION & Co., Soho-square.

This Catalogue of ninety large pages is one specially prepared for amateurs. The selection of articles here catalogued has been made

with judgment, for we cannot discover anything whatever conducive to amateur practice, from books of instruction to complete outfits, apparatus in whole or in part, that has been omitted—view finders, levels, plumb indicators, flash lights, stands, lenses, cameras, printing frames; but it is impossible here to enumerate a tithe of all that is to be found in this goodly work, which is profusely illustrated and, we may add, admirably printed on fine thick paper in the best style of the book-maker's art. Catalogue-making seems to be becoming elevated into an almost fine art.

THE EIKONGEN DEVELOPER.

WE have received from Messrs. Marion & Co., Soho-square, the sole agents, a sample of this newly discovered developer, which is now introduced into this country. Following the directions sent with the package, we dissolved the eikongen and developed not only negatives but transparencies and bromide prints most successfully. Although our trials have been too limited to warrant our saying much concerning it at present, we are safe enough in stating that we are quite charmed with it.

A NEW WASHING TANK.

By PERKEN, SON, & RAYMENT.

THIS tank is one of the "nattiest" we have had the pleasure of using, and it answers equally well for prints and plates. It is square in form, and is made of stout japanned tinware. There is a false bottom a little distance above the real one, and this false bottom has a divisional aperture in the centre running from end to end, immediately below which is a perforated tube through which the water is admitted in small jets, by which the prints (when it is devoted to print washing) are kept in a state of constant motion. The waste water is drawn off through a tap placed at the bottom, which is slightly V-shaped. The whole is so constructed that even with the slightest admission of water a like quantity can be drawn off after it has done its work, the quantity in the tank standing at any height determined upon.

For washing negatives, a light portable frame with adjustable grooved ends and sides is inserted in the tank, and the water keeps up a constant flow through them.

PATENTS COMPLETED.

IMPROVEMENTS IN FRAMES AND STANDS FOR PHOTOGRAPHS AND OTHER PICTURES.

No. 12,340. CARL SCHUBÖ, Offenbach-on-the-Main, Germany.—*June 29, 1889.*

THIS invention relates to frames and stands for photographs and other pictures, and has for its object to enable any person, without possessing any previous experience in the mounting of pictures, to place a picture in the frame or stand and remove it again in an easy and convenient manner.

According to the said invention, the frame or stand is not a firmly connected whole, but consists of two parts united by a spring hinge.

The improved stand constructed according to this invention can be made in the form of an easel. With its lower part is connected, by means of a hinge, a support which enables the stand to be put in an upright or inclined position.

A cross piece arranged on the said lower part forms a kind of channel in which the photograph or other picture and the glass plate for covering the same are placed. The upper part of the stand, which is connected with the lower part by the spring hinge, is turned backwards when the photograph or other picture is to be mounted with a glass plate.

After the picture has been placed in the channel formed by the aforesaid cross piece, the upper part of the stand is simply released so that it is moved back to the original position through the medium of the spring hinge, the upper edge of the picture and glass plate being covered by an upper cross piece provided on the upper part, thus giving the picture the necessary hold.

In another arrangement the upper cross piece of the frame or stand for the picture is connected with the lower part by means of two spring hinges, arranged at suitable points so that it can be turned back. The vertical frame parts are made hollow at their rear side, so that, with the cross piece to which a support is attached, a groove is formed into which the picture and the glass plate are slid. This having been effected, the upper cross piece is released, whereupon it is caused to move back to the original position by means of the spring hinge, which completes the framing of the picture.

In frames which do not possess the cross piece for the support, I provide, in the vertical frame parts, grooves into which the picture and the glass plate are slid in lieu of the said channels.

Frames and stands constructed as above described have the advantage of enabling photographs and other pictures to be mounted and dismounted by any person, and readily exchanged.

IMPROVEMENTS IN DARK SLIDES FOR PHOTOGRAPHIC PURPOSES.

No. 12,438. FRANCIS BEAUCHAMP, High Cross, Tottenham, Middlesex.—*June 29, 1889.*

IMPROVEMENTS in dark slides for this purpose. I provide the dark slide with one or two rollers with pinions fixed thereon, working into a rack; the said rollers are provided with a blind to wind up or down automatically, or by hand or a push piece, which by pressing unrolls the blind and covers the plate, and when released the blind rolls up and the plate is exposed; the said push piece is provided with an ordinary catch, or a cord to take the place of the push piece to answer in the same manner. I sometimes use one or two doors or flaps to open or close inside the camera, by moving a lever or button connected to the door or doors at the side of the dark slide, it enables the operator to expose or cover the plate instantaneously, thus dispensing with the inconvenience of drawing the dark slide to expose the plate, which must be done with the one now in use. This arrangement entirely prevents any light from entering the camera. The dark slide can be made to carry one two or more plates.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

JULY 23,—Mr. Leon Warnerke in the chair.

MR. A. COWAN showed some plates that had been equally exposed under a sensitometer and developer for an equal time with different re-agents, one of which was the substance called Eikonogen, and the others respectively ferrous oxalate, pyro with meta-bisulphite, and hydroquinone. The highest number was obtained with the Eikonogen. An advantage with the new developer was that it did not oxidise after the addition of the alkali. For chloride plates the developer was too energetic unless restrained with bromide, when the result, an example of which was shown, was very satisfactory, both in colour and purity of the transparent portions.

MR. W. E. DEBENHAM thought that the Eikonogen-developed plate looked more pushed than the others, and inquired whether if the pyro-developed plate had been kept longer in the solution, or the meta-bisulphite of potash had been omitted, as high a sensitometer number might not have been obtained as with the Eikonogen.

MR. COWAN considered that the developers were fairly tried. He also showed bromide prints developed, one with ferrous oxalate, and the other with Eikonogen. The surface colour given by the latter was brownish, and, he thought, the more pleasing colour of the two. He next showed two prints on opal developed on gelatino-bromide; one print was toned with gold, and the substitution was so complete that the picture might be regarded as permanent. The toning had been accomplished with acid chloride of gold, and had taken a whole night.

MR. E. CLIFTON, referring to a suggestion that the Eikonogen developer consisted essentially of pyrocatechine, inquired whether the solution was of a brownish colour.

MR. COWAN replied that it was perfectly green.

MR. CHAPMAN JONES said that the substance had been stated to be a derivative of naphthaline.

MR. CLIFTON inquired how many plates could be developed in the same solution.

MR. COWAN replied that he had tried eight successive plates in a quantity of solution so small that he could scarcely get it to cover the last plate; nevertheless, that plate came out like the others, except that it required three times as long to develop.

THE CHAIRMAN inquired whether any of the members knew of a system of toning bromide prints so as to resemble the colour of albumen gold-toned prints, and, receiving no reply, said that he had done it by first converting the image into a chloride by means of a solution of chloride of copper; then, after well washing, it was developed in the light with a weak iron developer such as was used for chloride printing, or, better still, with hydroquinone used very weak. This proceeding gave a red image that was amenable to the ordinary gold toning. He had also used a solution of bichromate and hydrochloric acid for converting the image into chloride, but it was not easy to wash out all the bichromate, therefore he preferred the chloride of copper.

MR. ARNOLD SPILLER recommended soaking in alum to get rid of bichromate.

MR. COWAN inquired what gold toning bath had been used.

THE CHAIRMAN said that he had used the old combined toning and fixing bath, but got best results with Obernetter's formula, containing sulphocyanide with hypo, &c. He thought it likely that the acetate bath would answer.

THE CHAIRMAN, referring to the Photographic Congress to be held in Paris, said that the promoters of it completely ignored the work that had been done

by the Photographic Society of Great Britain. Their method of proceeding, too, he criticised. First, he said they sent him an invitation to attend the Congress, but if he wished to avail himself of it he found that he must notify that by June 1, and send a fee of ten francs. This he had done, and received a ticket which mentioned that the French nation was exceedingly hospitable; nevertheless, he could not obtain admission to the Congress without paying for admission to the Exhibition. They managed things differently in Moscow, where delegates to the number of three hundred were entertained free of charge at the hotels, and twelve large carriages were placed at their disposal for visiting various places of interest. At Paris there was nothing of that kind. There was to be a banquet certainly, but the tickets were charged thirty francs each. He had yesterday received a programme of the questions proposed by the Committee of Organization of the Congress, and read some of the recommendations therein contained. The first was, that for the standard of unity of light the acetate of amyl lamp should be selected, and reasons given were that the acetate of amyl could be found everywhere, which was not true, and that the lamp could be found everywhere, which was also not true.

Mr. SPILLER said that he had used the acetate of amyl lamp, and found the light given to equal 8 of the English standard candle. Mr. Rawson had found the light to be 78, which was close to the same result. The lamp worked fairly with care, but the difficulty was that acetic acid was given out, which corroded the lamp; and it ought, in fact, to be made of porcelain throughout instead of metal. He thought the Pentane standard to be preferred. The lamp for this was formerly very expensive, but was now very much cheaper. Pentane was a very light paraffin, lighter than benzoline. The next point, Mr. Warnerke said, was the unity of mole of determining the sensitiveness of photographic preparations. This question it was proposed to solve by using various shades printed on paper, a plan which he certainly did not think highly of. Then came uniformity of measuring focal length of lenses. What did it matter what method was adopted for this purpose? Then came uniformity in the indication of the photometric effect of diaphragms, for which the recommendation was to take the focal length of the lens divided by 10 as unity, a number which several of the members considered too high, and preferred the Society's standard of one-fourth of the focal length. Then there was uniformity in measuring the speed of shutters, and means of adapting different lenses to different cameras; and a uniform set of sizes for photographic plates, some of the sizes being, in centimetres—9×12, 12×18, 18×24, 24×30, and 36×48.

It was pointed out by several members that these sizes did not bear a common proportion, but that whilst for certain sizes the proposed sizes were narrower than the usual proportion, others were broader, and that it would be better to have a set of sizes having a common proportion, or to have two sets, one broader and the other narrower throughout.

The next point was unity in expression of photographic formulae, for which the decimal system was recommended.

Mr. T. Bolas said that for weighing out quantities the decimal system was very bad, one of the worst. If any quantity had to be divided by four, three figures were at once required.

On the proposition that for unity in the denomination of photographic processes these should all commence with "photo" and end with "graph," leaving the intermediate letters to describe the particular method, the members considered that it would be too cumbersome.

On the last question, that of property in the negative, Mr. DEBENHAM thought that with regard to portrait negatives, the understanding that generally existed—namely, that the property in the negative was the photographer's, but the right to use it was joint, that is, it could only be printed by mutual consent—was a fair and just understanding. This view met with general approval amongst the members present.

Mr. Spiller had recently been shown some photographs by Dr. Eder which were produced by the application by photography of a protective coating to a sheet of flashed glass. The coat of colour was then etched away by hydrofluoric acid where not protected by the image, and the result was very good.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JULY 18.—Mr. A. Mackie in the chair.

A communication from the Photographic Convention of Great Britain was read, which contained an invitation to the Association to send delegates to the Conference to be held from the 19th to the 24th of August next, and Messrs. A. Haddon, A. Cowan, and Thomas Bolas were accordingly appointed delegates.

Samples of a powder for developing, called Eikonogen, were distributed amongst the members. Mr. Cowan, who had experimented with the substance, spoke highly of it.

Mr. Cowan next showed some pairs of bromide prints on opal glass; one of each pair had been toned with gold. To show that the toning was a complete substitution, rendering the photograph, in fact, a permanent gold one, a toned and untoned plate were placed together in a dish of slightly diluted nitric acid. The image of the untoned plate disappeared almost immediately, whilst the toned image remained unchanged until the acid loosened and dissolved away the gelatine itself. Mr. Cowan's method of procedure was to first clean the gelatine off the film by the application of dilute hydrochloric acid—five or ten per cent.; the plate was then laid in a solution of chloride of gold, one grain; water, four ounces; and hydrochloric acid, four minims. The toning was slow, in order to ensure its thoroughness. He left the plate in for twelve hours, but he believed the toning was complete in four or five hours. If taken out before completion the image would be partially dissolved by nitric acid and could not be relied upon as permanent. After toning, the plate was again passed through the fixing bath to dissolve the chloride of silver, which would otherwise darken in the course of time.

Mr. Haddon said that he had experimented with some prints toned by Mr. Blanchard's plan, and found that they did not resist the re-agents which distinguished silver from platinum prints. The toning appeared to be superficial, and there was no such thorough substitution of platinum for silver as to confer permanence upon the photographs. He had used as tests sulphuric acid, nitric

acid, hydrochloric acid, solution of hyposulphite of soda, and solution of common salt. In the three acid solutions the image almost disappeared, whilst even a continuance in the hypo solution was nearly as bad. He then produced a bottle of chlorine water and immersed in it portions of a true platinum print and of one of Mr. Blanchard's toning. The latter almost entirely disappeared, whilst no change was noticeable in the platinum print.

Mr. ANDREW PRINGLE had found that platinum prints might be left in these testing solutions *ad libitum* without fading.

Mr. HADDON said that he could not very well reconcile these results with Mr. Levy's statement that the toned image contained sixty per cent. of platinum. The tests he had used were mostly similar in kind to, though stronger in degree than, those actually likely to affect photographs. In places by the sea there would be at times a certain amount of salt deposited, in houses where gas was burned sulphuric acid was formed, whilst prints were liable to contain hypo from imperfect washing.

The CHAIRMAN would like to know the resistance of gold-toned prints to these tests.

Mr. PRINGLE said that the action of gold toning was not perfectly understood, one party holding that there was an electrolytic action, whilst another party maintained that it was a substitution process. He understood Mr. Blanchard to say that in his method the action was one of substitution.

Mr. W. E. DEBENHAM said that there was no doubt that in such examples as those shown by Mr. Cowan the action was a substitution one very thoroughly effected, and that the image then became a gold one and was permanent. With gold or platinum used thus the image was permanent, but when either metal was deposited superficially, as in ordinary toning, so as merely to change the colour of the image, there was not enough deposited to confer permanence. It appeared, however, from some experiments made by Mr. W. K. Burton that it was possible to carry the ordinary toning process so far as to deposit enough gold to render the image permanent, and that without causing the print to become grey and cold, as was generally the case when toning was carried beyond the usual stage. An essential condition insisted upon for this result was that free silver should be thoroughly removed by washing before the print was put into the toning bath.

Mr. PRINGLE had followed Burton's experiments, and his results were in perfect accordance therewith. If a print is red before commencing toning you can go on further with the deposition of gold before it becomes blue. A strong toning bath by acting rapidly gave blue tones, but with a weak one the action may be carried on until much more gold is deposited before a blue colour is obtained.

Mr. DEBENHAM said that the silver deposit in certain cases took on a colour somewhat similar to that of a gold-toned print without any gold being used at all. He had found this notably the case with citro-chloride gelatine plates printed out on opal glass if the plate had been kept for some time before being printed. That the colour was due to the keeping of the plate was shown by the fact that plates prepared with the same emulsion gave when fresh the ordinary red image unless toned. He would ask whether Mr. Cowan had noticed the same peculiarity in kept plates.

Mr. Cowan had found the same effect as that described by Mr. Debenham.

The CHAIRMAN had found that ready-sensitized paper when very old, toned with difficulty but gave more intensity, so that much thinner negatives could be printed with it than with the same paper used fresh.

Mr. PRINGLE would have expected the contrary. When using old paper he always added more alkaline carbonate to the fixing bath to get purer whites.

Mr. S. G. B. WOLLASTON adopted the same practice.

The CHAIRMAN would like the opinion of the members as to whether there was a characteristic colour, as sometimes stated, in prints toned with gold solution neutralised by the various salts used for the purpose, such as borax, carbonate of soda, &c.

Mr. PRINGLE thought that the characteristic of borax was to give a warm brown, and of carbonate of soda was a purplish colour, but with acetate any colour could be obtained.

The CHAIRMAN said that he had used borax, carbonate, tungstate, and acetate of soda, and if each was carried on to the same degree he could never detect the difference. He wished to call attention to the extreme inaccuracy of the literature of photography on the subject of the toning bath. When several formulae were given it was said of some of them that they were ready for use at once. The fact was that no toning bath was ready for use at once. With different adjuncts different times were necessary for the bath to get into condition, and if that condition was required quickly it could be much hastened by heat. The gold should be in such a state that the yellowish colour of the solution was giving way to a purple, and then it was ready for use. The gold should not have precipitated but be on the verge of precipitation.

Mr. DEBENHAM's views were, generally speaking, those of the Chairman. He had, however, found that a gold bath had passed the ripe stage and entered on a condition of refusal to tone without having precipitated; the metal was in the solution but not in a condition to tone.

Mr. P. EVERITT then read a paper on *The Right to the Negative*, in which he took the view that the negative belonged to the sitter both by law and right, and that the photographer ought to give it up when required.

Mr. DEBENHAM maintained the view which he had expressed in a recent controversy, that the property of the negative was the photographer's, but the use of it was joint with the customer. According to this view, which was in accordance with universal or almost universal practice, neither photographer nor sitter could use the negative without mutual consent. If there was any injustice in this arrangement, as implied by Mr. Everitt, he would like to have it pointed out. As to the exposing of a print as a specimen, that being so much the practice, he thought that consent of the sitter might be assumed unless, as was sometimes done, a wish had been expressed to the contrary. Of course, in assuming the sitter's consent, the photographer should be bound to withdraw the specimen at any time it required to do so.

Mr. F. A. BRIDGER said that the custom of the trade was for the photographer to retain the negative, and that was the understanding upon which he fixed his charges.

Mr. Cowan added that when a sitter stated, to begin with, that he required

to have the negative, the photographer made an extra charge to compensate him instead of relying upon the supplying of duplicates.

The CHAIRMAN followed on the same side, and the meeting was adjourned at rather a late hour.

It was announced that on August 8 Mr. Friese Greene would exhibit and demonstrate his process of photographing upon opal cards.

NORTH LONDON PHOTOGRAPHIC SOCIETY.

JULY 16.—Mr. W. T. Coventon in the chair.

The HON. SECRETARY read a letter from the Secretary of the Convention, and distributed copies of the conditions.

Mr. M. C. Wood showed a photograph on opal which had streaks across the film; this was thought to be caused by a deposit, and was partially removed by rubbing. It was recommended to put it in the hypo bath again and well wash it.

Mr. J. Oakley showed some local views which he had purchased for sixpence a dozen, and which were apparently by a mechanical printing process.

Mr. J. Carpenter showed a negative on a ground glass plate in which there was a distinct halation on the roof of a church.

This led to a discussion on halation, in which several members took part.

Mr. OAKLEY showed a photograph of the interior of a church which at first had the bars of the window obscured by halation, but on rubbing gently with methylated spirit it showed every detail in the window. He considered that these parts were so much over exposed that they were blocked up, and did not think it to be due to reflection from the back of the plate.

Mr. W. BISHOP considered that the particles in the atmosphere absorbed the light and an overlapping of rays took place.

The HON. SECRETARY called attention to the case of a church steeple with the sun directly behind it; the part near the sun would frequently appear narrower than the other parts close by, thus proving that there is sometimes an overlapping of rays of light.

Mr. A. C. COSSON found a difficulty in getting even results when reducing halation by rubbing with methylated spirit.

Mr. OAKLEY thought that this was due to there being more spirit on the rag when the rubbing was first commenced, and it reduced this part quicker.

The HON. SECRETARY advised a brush charged with bromide of potassium or other restrainer for treating windows after they were sufficiently developed, as a much finer result could be obtained in this way.

It was resolved that the Saturday outings should be continued, and an excursion was arranged to Elstree for Saturday, July 27. Trains from Moorgate-street Station at nineteen minutes past two, or St. Pancras at three minutes past three.

The next meeting will be on August 6, and will be a general technical meeting.

LEWES PHOTOGRAPHIC SOCIETY.

JULY 16.—The President in the chair.

Two members were elected.

A resolution was carried in favour of the adoption of the metric decimal system by photographers.

The Hon. Secretary was appointed the delegate to represent the Society at the forthcoming Convention to be held in London in August.

The HON. SECRETARY then read a paper on *The Artistic Side of Photography*, which was supplemented by a collection of photographs by Mr. H. P. Robinson, Mr. F. M. Sutcliffe, and the Hon. Secretary, and by a few etchings and engravings.

A discussion followed.

Work was shown by members who had attended the excursions held on June 19 and 22.

On the 22nd the members of the Brighton Society visited Lewes and were conducted to the principal places of interest in the town, including the Castle and Priory ruins. The party afterwards adjourned to the Glee Room, where they were met by other members and friends, and witnessed a lantern slide entertainment.

The next excursion will take place at Sheffield Park and Fletching on Friday, August 2.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

JULY 18.—Mr. W. J. Harrison, F.G.S., in the chair.

The HON. SECRETARY read a letter from Mr. George Bankart, awarding the prize for the best picture (taken on the excursion to Shakesperian villages) to No. 9. On the sealed envelopes being opened the winner was found to be Mr. E. C. Middleton.

Excursions were announced for the half day to Alton Towers on August 10; to Stratford-on-Avon on August 24.

The CHAIRMAN, as leader of the excursion to Warwick, read his report; it showed that thirteen members attended and eighty-five plates were exposed, principally Hford and Thomas's.

The HON. SECRETARY reported that he had received copies from the editors of *The Lantern and Entertainer* (Mr. J. Hay Taylor), and *Photographic Review* (Mr. Thomas Bolas), which had been placed on the tables of the Club Room.

Mr. G. S. SERSCHALL delivered a practical and theoretical paper on *Portrait Painting as applied to Photography, with Illustrations, &c.* [see page 489].

The paper for August 15 is by Mr. G. Edmonds, on *Light, Lenses, and Stops.*

MANCHESTER PHOTOGRAPHIC SOCIETY.

JULY 11.—Mr. T. R. Copley in the chair.

Minutes read and confirmed.

Mr. J. H. Orrell was elected a member.

Question box:—"Has any member tried the new 'water developing plates'?"

No reply.

"Does the sodium hydrate developer affect the skin?"

Reply from several members:—Not to any serious extent.

"What is the best way of holding back the high lights when using sodium hydrate and hydroquinone as a developer?"

Several members replied to this, giving various opinions; the discussion, however, soon drifted.

Mr. HEYWOOD said chloride of lime was a capital reducer.

"Why should not this Society possess an enlarging lantern or enlarging camera to lend to the members on payment of, say, two shillings per week?"

Here a lengthy discussion took place as to the conditions and regulations for lending such apparatus.

The HON. SECRETARY (Mr. W. I. Chadwick) quite approved of the Society not only possessing enlarging apparatus but many other things, if they were provided with a dark room and other conveniences at the home of the Society, and to be used there; and, indeed, he did not see why such conveniences could not be provided. It was simply a question of expense. If the Society could not at present afford permanent rooms, for his own part he would say dispense with the teas at the monthly meetings, and the thing is done.

It was resolved that the Council take into serious consideration the advisability of purchasing suitable enlarging apparatus for the use of the members.

Mr. W. H. Farrow exhibited some exceedingly interesting specimens of "pin-hole photography." In the lid of a cardboard box, about $4\frac{1}{2} \times 3$ inches, twelve holes were made by the point of a needle. The box inside was divided into twelve sections by strips of cardboard, and a sensitive plate placed at the back or the bottom of the box, which was about two inches deep. The exposure in a bright north light for four seconds produced a very fair portrait; distance from the sitter, about six feet.

Mr. H. Smith exhibited some negatives which he had taken in Paris, using a Kodak and stripping films. Although the results were not satisfactory, they were interesting. One of the negatives Mr. Smith had expanded by hot water, and managed to get a fairly good printing negative about 4×3 inches; but this method of "enlarging" was not always a success. Hydrochloric acid helps it a good deal, and the negatives must be very dense to begin with, for they lose much of their density in the stretching process. Another interesting result was a stereoscopic slide made by the Kodak. After the first exposure had been made, the instrument was held steady; Mr. Smith then moved to the right a short distance, "pulled a string and touched a button," and the thing was done so far; the rest he did at home.

The Hon. Secretary exhibited six negatives to illustrate various methods of development. They were all on the same brand of plates; the subject, exposure, and general conditions were the same. No. 1 and No. 2 were both developed by pyrogallie acid, to which had been added meta-bisulphite potash in the proportion of four to one of pyro, the only difference being in the alkali—for No. 1 ammonia was used, and for No. 2 carbonate of potash. There was not very much difference in the result; the members considered, however, that developed by ammonia to be the best.

The next four negatives were all developed by freshly mixed pyrogallie acid without any preservative, the difference alone being in the accelerator used. For No. 3, ammonia was used; No. 4, carbonate potash; No. 5, sodium carbonate; No. 6, potash and sodium carbonate together in equal quantities. In this case, as in the former, No. 3 (ammonia) was considered the best negative.

Mr. ABEL HEYWOOD, jun., called attention to an exceedingly good paper by Mr. John Brett, published in the *Camera* of last week.

Attention was called to the outdoor meeting to take place on July 20 for Trentham.

Mr. H. SMITH, the leader, said it was important he should know the number of members who intended going.

Mr. BLAKELBY also called attention to the Bank Holiday trip to "The Dukeries," of which he was leader. Unless fourteen members could decide to go, it was little use taking any further steps. Several, however, gave in their names.

Mr. W. B. WOOD humorously remarked he always found Bank Holiday at such places as photographers liked to go to a capital time for "figure subjects;" if they were not all artistic, there was at any rate variety.

Correspondence.

Correspondents should never write on both sides of the paper.

FILM CARRIERS.

To the Editor.

SIR,—I see in your issue of July 19 a letter from Mr. W. B. Bolton, in which he, instead of replying to anything contained in my letter to you, goes out of the way to give erroneous replies to a letter I sent to him. He asks the reason I wrote to you; I think the reason must be apparent to any one who has read the letter, except to Mr. Bolton himself. I need not here again repeat the beginning of my letter in your issue of July 12.

When Mr. Bolton's advertisement first appeared, giving a description of the Double Carrier, I wrote and told him that I had already patented this form of carrier. He replied that "his was quite different," which is not the case; and he does not, in the face of my last letter even, offer to contradict this. The advertisement also stated that on receipt of "a penny stamp" particulars would be sent. I enclosed a stamped envelope and my own circulars, but Mr. Bolton has not had either the common fairness or business tact to send these particulars to this date. He then quotes a few words from my letter to him, saying that Samuels "does not in his patent claim film carriers." But he quite forgot to

add the following few words, "except in combination with his changing back."

I said in my letter of the 12th, that "Neither the single nor double carriers are new;" the fact being that they date long previous to Samuels' patent. In your leader of the 12th, you draw attention to Merritt's patent of 1854. I had the curiosity to look it up, and find it is for a changing back, à la Samuels, with a silver bath and frame for dipping the plates in the bath. But this has very little relation to the carriers now under discussion, which are not for that purpose; neither has his two pieces of glass with the sensitive paper gummed at the edges to keep the glasses together anything in common with metal film carriers for ordinary double backs.

In 1873 the late Mr. Aird invented a camera on the changing-back principles with plate carriers, as claimed for Mr. Samuels. In the early part of 1875 he, at my request, read a paper before the Edinburgh Photographic Society descriptive of his camera. This paper was fully illustrated with drawings and sizes of parts. The paper, with drawings and descriptions, was published in THE BRITISH JOURNAL OF PHOTOGRAPHY at the time, and will be found in the volume for 1875. From these drawings M. Jonte, of Paris, made, shortly after, an improved "Aird's Camera," with several additions; for instance, an additional part which indicated, by puncturing a strip of paper, the plates that had been exposed, showing also the number of the plate exposed. Mr. L. Warnerke had one of these cameras, a beautifully made one, for plates 9 x 7, and showed it at the Photographic Exhibition in Edinburgh, 1876. The original camera by Aird was also shown there, and both will, I think, be found in the catalogue, of which I have a copy. Should any further proof be required as to the existence of these cameras and carriers, the original camera made by Mr. Aird is still in existence, and in possession of one of his friends, who, I have no doubt, will show it to any one interested. Further, several cameras were made at the time on both Aird's and Jonte's principle, and I have in my possession at the present moment one of the Jonte principle made in 1877, which I can show at any time. I may here say, further, that there are several detective cameras at present in the market with carriers and without double backs, which, if not exact copies of Aird's camera, are at least very near it.

What Mr. Bolton further writes about his carrier is not worth notice, and I have already disposed of it in my former letter. But what I wrote about patent law he evidently does not relish, it being a too solid and indigestible form for him; and what he quotes as to "a valid patent, &c.," is perfectly sound. Though he may think it "cheap," this and more Mr. Bolton may have "cheap," in fact for "a penny stamp" in many of the patent agents' pamphlets. Surely he will admit these men know something of their business.

In conclusion, whether any of these patent claims be good or not, I do not look on "film carriers for ordinary double backs" as of any great importance, as if the use of films becomes general, as I think it undoubtedly will, the use of double backs for plates will correspondingly go out of use, and films be exposed either in thin film slides expressly made, or in changing backs carrying a quantity of films; or if celluloid can be made thin enough, as I already hear it is, roller slides will come more into use. But whatever form it may assume, it will, without doubt, be governed by the universal law of the survival of the fittest.—I am, yours, &c.,

J. M. TURNBULL.

6, Rose-street, Edinburgh.

DISCOVERIES.

To the Editor.

SIR,—I have just read the following, over the signature Henry J. Newton, in the last number of the JOURNAL. "Photography is one of the three great discoveries of this century—the steam engine," &c.

Does he really mean to say that the steam engine was discovered during the present century, or does he mean the locomotive?—I am, yours, &c.,

J. E. G.

Westward Ho! July 22, 1889.

[We must leave Mr. Newton to "cash his own paper." But we imagine that more than three great discoveries have been made during this century.—Ed.]

MR. ANDREW PRINGLE AND THE STEREOSCOPE.

To the Editor.

SIR,—Mr. Pringle proposes to distribute copies of his article on the stereoscope among the members of the Manchester Photographic Society, so that they may judge for themselves as to whether I have garbled him or not. I could wish for no better plan. I contend, however, that such extracts as I gave require no context to modify them; what I represented the character of the paper to be, so far as it referred to the stereoscope, that I believe it to be. The "Pharaoh's serpents" business and such-like are not modified, and cannot be modified, by any context.

A slipshod, misleading paper, such as that of "A. P.," with just a substratum of fact in it, and nothing more, if applied to an individual

would be a libel; it is no great stretch of figure, then, to designate the article a libel on the instrument treated of.

So far as I understand Mr. P., he complains that I did not criticise his notions on art. Although I believe those notions (if the article in question at all represents them) to be just as shallow and as vulnerable as his opinions on binocular vision and the stereoscope, the subject is Mr. Chadwick's, not mine, and I leave him to deal with it.

It is refreshing at my age to be taken for a beginner; I fancy I began this life long before "A. P.," and was a photographer when he was in petticoats, but, as I have never seen Mr. Pringle, I may be misinformed as to this.—I am, yours, &c.,

ABEL HEYWOOD, JUN.

Higher Broughton, Manchester, July 20, 1889.

To the Editor.

SIR,—I ask you to give me space for a few words in reply to the letter of Mr. Andrew Pringle, published in THE BRITISH JOURNAL OF PHOTOGRAPHY last week. I confess it is sometimes inconvenient for readers to follow an argument or a controversy conducted in two different newspapers. Mr. Frank M. Sutcliffe published an article in your contemporary, *Photography*, on the "Influence of the Stereoscope," to which, it will be remembered, I replied through the columns of THE BRITISH JOURNAL OF PHOTOGRAPHY, at the same time giving, I believe, sufficient quotations, context, and argument of Mr. Sutcliffe to make my reply understood; Mr. Pringle then took up the cudgel for Mr. Sutcliffe in your contemporary, to which Mr. Heywood replied at the meeting of the Manchester Photographic Society, June 21, 1889. Until we met at that meeting I had not seen Mr. Heywood for over a month. I did not know he had read a line of the correspondence that had taken place until the day before that meeting, when I received a short note from him, stating that if there would be any time to spare at the meeting, he wished to say a few words in reply to Mr. Pringle on the "stereoscope." Personally, I did not consider it worth my while to reply to Mr. Pringle, having already done so to Mr. Sutcliffe, indeed I have not the time or inclination to reply to all the foolish things one reads.

Mr. Pringle's remark that he "was not aware that I had any other than a scientific interest in stereoscopic photography," should be taken as a compliment to me, for any one to have read my articles on "Stereoscopic Photography," or the stereoscope, without detecting the slightest trace of anything but "the pure scientific interest" was just my intention.

But one wonders now if when Mr. Pringle read the last communication to photographic literature by Mr. Dallmeyer, if he (Mr. Pringle) was aware that that gentleman sold photographic lenses. I assure you, sir, that I never made the same mistake when reading the name of Andrew Pringle—not even when it was printed "Andrew Pringle, Esq." You know the old proverb, "People who live in glass houses, &c. &c." Before concluding, I must acknowledge the compliments which Mr. Pringle has paid to the Manchester Photographic Society. I do not remember that we made any special fuss of him, and he need be under no particular obligation. We endeavour always to treat our visiting brethren with the same kindness, hospitality, and friendship as was accorded to Mr. Pringle, and which, I assure you, would be extended to him again should he choose to visit us.—I am, yours, &c.,

W. J. CHADWICK.

THE FRENCH EXHIBITION.

To the Editor.

SIR,—I read in THE BRITISH JOURNAL OF PHOTOGRAPHY of July 19 a most unfounded, unwarranted, and, above all, uncourteous attack on your Paris correspondent by one Mr. E. Lisk, of Amières.

I have not the intention to enter into a polemic with that personage, who shows as great an ignorance of photography as he does of the use of refined language. I only need draw the attention of the enlightened readers of THE BRITISH JOURNAL OF PHOTOGRAPHY to a letter published in the same number, that of Mr. York (a gentleman known to all). This letter bears out fully the truth of my assertions.

As to the twenty-five centimes, Mr. Lisk must be very unacquainted with printing not to see that it was a printer's error.

I will not deign to refute the multitude of errors he has thrown into print. I will rectify one lest some person (having confidence in his word) desires to make the twenty-four negatives of which he speaks from eight to two o'clock (a day). I warn that person that it is not twenty francs, but forty francs fifty centimes he would have to pay.

Moral: Before correcting others be sure not to make "wrong assertions" yourself.—I am, yours, &c.,

PROFESSOR E. STEBBINO.

196, Rue Legendre, Paris.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting of this Club, July 31, 1889, will be on a paper to be read by Mr. C. Ray Woods on *Photographic Experiences at the Cape*. Saturday outing at Richmond. Bank Holiday outing at Godalming.

Exchange Column.

*. * No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

A banjo, seven strings, machine head, nickel hoop and rim, for half-plate camera and slides.—Address, J. J. BAYFIELD, 5, Upper Hill-street, Richmond, S.W.

Wanted, photographic apparatus in exchange for gentleman's eighteen carat single stone diamond ring, cost eight guineas.—Address, G. I. TUKERMAN-street, Blackburn.

Will exchange Sandringham Club tricycle (Coventry Machinist Company) for full-plate camera, three double backs.—Address, W. ATKINSON, Photographer, Barnard Castle.

Wanted, modern work on chemistry or electricity in exchange for Burton's Photographic and Photo mechanical Printing.—Address, C. FARLOW, 9, Malvern-terrace, Barnsbury, London, N.

Wanted to exchange, Kershaw's instantaneous shutter and pneumatic tube for posing chair with two or three backs. Difference adjusted.—Address, B. H. GIDNEY, Artist and Photographer, London-street, Basingstoke.

Wanted, whole-plate camera with rapid rectilinear lens, tripod, and double back, first-class condition, in exchange for two dissolving-view lanterns in case, by Milliken & Lawley.—Address, A. J. TILLY, 33, Briggate, Shipley, near Bradford.

Wanted, 12x10 modern portable camera, three double backs, tripod, and rapid rectilinear lens, or anything useful in photography, in exchange for first-class modern tricycle complete, also bicycle. Offers invited.—Address, ROBERTSON'S STUDIO, Morcambe.

Will exchange 15x12 rolling press, steel plate between rollers; embossing press by Marion, two cabinet, two C.-D.-V., oval, and cushion-shape dies; Entekin's cabinet-size burnisher. Any one of the above for balustrade by good maker, Optimus half-plate Euryscope, or Optimus wide-angle half-plate, or rapid rectilinear half-plate.—Address, J. EDGE, 380, Stretford-road, Manchester.

Answers to Correspondents.

*. * Communications relating to Advertisements and general business affairs must be addressed to "H. GREENWOOD & Co., 2, York-street, Covent Garden, London, W.C."

All matters for the text portion of this JOURNAL, including queries for "Answers" and "Exchanges," must be addressed to "THE EDITOR," 2, York-street, Covent Garden, London, W.C. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.

PHOTOGRAPHS REGISTERED:—

Messrs. Mackintosh & Co., Kelso.—Groups of the celebration of the Ter-Jubilee of the Secession Church, also groups of the ministers who conducted the same.

SAM BEEVERS.—See article by Mr. Thomas Seaton in our last issue.

GRAMME.—Metric weights and measures may be obtained from those who supply chemical apparatus.

H. T. YOUNG.—There are now no makers of such plates, but to a clever photographer their preparation will not entail any difficulty.

W. P. ADAMS wishes the address of a firm making celluloid for negative films. He is anxious to obtain samples unemulsified for experimental purposes.—Perhaps some one will respond.

W. RICHARD.—Mix the colour with albumen and apply in the ordinary manner. Lubricate the prints with a weak solution of Castile soap in alcohol and the colour will not come off in the burnishing.

STUDIO.—You may use the term "Patronised by the Queen," and every member of the Royal Family collectively and individually, if they have patronised you; but beware making use of the Royal Arms.

A. J. C.—The Euryscope of the makers named will, with full aperture, work quicker than their rectilinear, but when stopped down to equal the latter in rapidity there will be no difference in their working.

J. BRUCE.—If you cannot get the prints flat and even enough for copying, the best plan will be to take the book to a bookbinder and get him to remove them, then take the copies and afterwards have them replaced.

BETA.—It is illegal to put the word "patent" on an article which is not patented, and the offender subjects himself to heavy penalties for so doing. It is also illegal to mark a picture "copyright," when no copyright exists.

R. STEWART.—We cannot, for fear of libel, publish your letter of warning against the individual advertising. People who buy second-hand apparatus from strangers ought to take such steps as will protect themselves other than post-dating money orders.

IN A FOC.—If the toning bath becomes discoloured and turbid, it shows that the gold has been precipitated. A dirty dish or bottle will cause the reduction, so will impure materials. Some kinds of paper are prone to cause a spontaneous reduction of the gold.

A. E. BULL.—Blue glass is seldom, if ever, used nowadays for glazing the studio. It was employed to a limited extent many years ago, but has long since been discarded. There is nothing better for the purpose than the ordinary sheet glass of commerce.

BRAZIL.—You cannot do better than place yourself entirely in the hands of the firm you mention. You can rely on their things being good.

FILM.—Celluloid and xylonite are similar compounds. Inquire of the British Xylonite Company, Homerton; they will probably make the articles to your order. We expect, however, you will have to order a large number at a time or they will not undertake the manufacture.

CAUSTIC.—The best plan will be to precipitate the silver in the metallic state by immersing a few pieces of pure zinc. Then well wash and redissolve in nitric acid. By the addition to the bath of nitric acid, a large proportion of nitrate of ammonia would be produced which would be very undesirable in the solution.

F. E.—If the white lac has become as brittle as you describe, it will be of no use for making negative varnish. If bleached lac is kept long in a dry condition it becomes "perished," and is then worthless. To preserve it in good condition, white lac should always either be kept in water or in a jar with a little water at the bottom.

NOVICE.—Let the proportion of bichromate to gelatine be such as will not allow the former to crystallise. Precise proportions are immaterial. Use hot water for development. Acetic acid will also answer. If you have access to our volume for 1883 you will find such optical articles as will probably serve your purpose; if not, write again and enclose envelope for private reply.

R. J.—You are clearly in the wrong, for you are not only exhibiting the portrait without permission, but against the wish of the sitter, as expressed at the time of sitting. That you have not yet been paid for the portraits makes no difference, as you can sue for the amount in the County Court. It looks like a case of obstinacy on both sides. But as, according to your own showing, you promised not to exhibit the picture, the proceeding is any thing but honourable.

W. DE FRERE says: "I have just purchased a set of cutting shapes and a Robinson's wheel print trimmer. This cuts the prints *cushion shape*. I am now told that pictures with the corners rounded off are not artistic, and if sent in to an exhibition for competition they would be condemned at once if trimmed in this manner, however good the subject might be. Is this a fact?"—Different exhibitions have different rules, but we do not remember any set rule that prints with the corners rounded off were inadmissible.

T. Y. HANSTOCK writes: "Can you tell me of any cement, or anything we could mix, for wooden tanks which hold hydrochloric acid, thirty Twaddle. I have tried tar, pitch, and oakum, but the tanks leak yet."—If pitch fails, which we should scarcely have expected had it been properly applied, try marine glue or paraffin. A great deal depends upon the tanks being well made in the first instance. Unless the wood be well-seasoned and carefully joined, it is next to impossible, with any cement, to prevent leaking when they contain acids.

T. J. writes: "Can you tell us the cause of the silver prints blistering? They are all right when we take them out of the soda fixing, but when we put them into the water for washing they go all over little blisters. Most of them disappear when they are burnished, but in many cases the prints are spoiled."—These blisters are often produced when the prints are suddenly transferred from a solution of one density into that of another; or from one of a certain temperature to that of a different one. Keep the fixing solutions and washing waters at the same temperature. Instead of taking the prints direct from the fixing bath and putting them into water, dilute the bath—say to one half strength—and allow them to remain for a few minutes before transferring to the water. Or when taking them out of the hypo, put them in a solution of common salt for a short time prior to commencing the washing.

BLISTERS writes: "Can you inform me how to prevent albumenised paper blistering? I have been sorely bothered of late with paper blistering; it generally occurs during the night in the washing. I have tried salt, ammonia, &c., but all to no avail; the prints blister up as large as walnuts. Can you also suggest anything to prevent the paper from stretching? I get great unevenness in the length of some prints."—This kind of blister is more prevalent in hot weather than in cold. Primarily, they are due to the paper itself, for it will be found on examination that it is not only the albumen that has separated, but that the fibrous surface of the paper has come away with it. If the paper be kept for a longer time before it is albumenised, the defect will most likely disappear; so, doubtless, it will if the albumenised paper be kept for some months. These particular blisters may usually be avoided by completing the washing in a short time. Long soaking enhances them. With regard to the stretching of the paper, all paper stretches when it is wet, but the expansion is always greatest in the width of the web. Longitudinally, it is very slight indeed. There is no way of avoiding this if the prints be mounted wet, but if they be cemented and allowed to dry, and the mount be moistened and the print rolled in contact with it, stretching may be practically avoided.

No. 1526. VOL. XXXVI.—AUGUST 2, 1889.

PORCELAIN PAPER.

ARISING out of the discussion which took place at the last reported meeting of the London and Provincial Photographic Association, on the occasion of Mr. Haddon having explained certain experiments, was the subject of a comparatively little known porcelain paper which, several years ago, flashed upon us with unwonted brilliance, obtained admiration wherever seen, and was withdrawn suddenly from public observation, owing to commercial unpleasantnesses, almost immediately after its introduction. This paper was pure and white, totally free from gloss, and by keeping the print on its extreme surface imparted a degree of brilliance otherwise unattainable, unless with paper coated with albumen. The shadows, consequently, were rich and deep, the whites and middle tints being delicate. From the fact of the surface resembling finely-ground porcelain, it almost naturally received the designation given it at the time—"porcelain paper."

Although the surface is hard and the texture firm—these to such an extent as to prevent the photographic image from sinking in—yet is it not so repellent of water as to prevent its being easily amenable to the action of the sensitising, toning, and fixing baths.

All those difficulties which operated to knock it on the head at the time of its introduction, and which, as we have said, had reference to a commercial disagreement, being now non-existent, and, moreover, the public taste being now cultivated into a preference for, or, at any rate, into a sympathy with matt surface prints, we see no reason why the porcelain paper should not be once more brought into public notice. Just at first, those who may care to try it will have to prepare their own paper, but as the operation is so easy and certain, and, unlike the preparation of sensitive dry plates, can be effected in a well-lighted room, we doubt not that those who do try will succeed perfectly.

While we write this we have not access to all the notes we made at the time when we last prepared paper according to this system, which, if not invented, at any rate was perfected by Mr. Brinckerhoff of New York, and who, when we last saw him, was getting into the evening of life. Still, sufficient will here be said to enable its nature to be well understood.

A sheet of any good quality of plain Saxe, Rive, or other photographic paper is coated with a warm solution of gelatine holding in suspension sulphate of barytes or finely-powdered kaolin. Upon raising the paper from this emulsion it is suspended in the air until dry, when it is immersed in a solution of alum, tannin, or any other substance by which gelatine is rendered insoluble. The body of the paper is thus imbued with the gelatine and its surface has a fine texture, the pores being all filled up.

When the paper is to be used it is salted by floating it upon a bath of chloride of ammonium and water, about four grains to the ounce of water. In this state it will keep well for many months. It is sensitised by being floated upon a bath of ammonio-nitrate of silver. An ounce of the nitrate is dissolved in sixteen ounces of water and strong ammonia added drop by drop, with constant stirring, until the dark precipitate at first thrown down is just redissolved. Although the way here described is that by which the singularly fine specimens alluded to were prepared, yet results indistinguishable from these may be produced by sensitising on a plain nitrate of silver solution, provided that after the paper is dry it is well fumed over ammonia, by which a great degree of richness is imparted to the tone.

After removal from the printing frame the proofs are washed first in plain water and afterwards in water containing a little chloride of sodium, say a grain to the ounce. Then follow toning and fixing, the prints acquiring a fine purple in the gold bath. On removal from the hyposulphite of soda it is recommended to wash the prints in three changes of warm water, followed by a prolonged immersion in cold water.

THE FRENCH PHOTOGRAPHIC CONGRESS.*

On the fourth question, "Uniformity in the mode of measuring the time of admission of light regulated by shutters," Colonel Sebert is again reporter. He commences by stating the necessity of setting on one side all efforts at measurement in which outside influences prevail, such, for instance, as photographing moving objects in which the actual value of the light passed through the lens is not given. The method to be adopted must be based solely upon the geometrical valuation of the different parts of the shutter, and on the mechanical determination of the law of its motion under different condition of regulation and with different diaphragms or openings. It is pointed out that it is not sufficient to measure the total time during which the shutter is open, but that it is necessary to take into consideration the constantly varying conditions of lighting that prevail during opening and closing, and to compare these, in so far as the actual light admitted is concerned, with an ideal shutter opening and closing *instantaneously*. The result of this comparison it is proposed to call the "co-efficient of utility," and to represent it by means of a figure always less than "1" and limited to one or two places of decimals. The total period from opening to closing of the shutter, if multiplied by the coefficient of utility, will then give the

* Continued from page 456.

absolute time-value of the exposure, and will render it easy to calculate with any kind of plate what stop to employ or what regulation to apply to the shutter. It is also proposed to require in future all makers of shutters to mark them not only with the "time of exposure," or total duration, but also with the coefficient of utility.

The additional remarks on the practicability of the suggested reforms, and on the purely mechanical methods of measurement, contain nothing novel or interesting.

The fifth and sixth questions are "A uniform and easy means of adapting different lenses to different cameras," and "Uniformity in the dimensions of plates," and these are dealt with by M. Franck de Villecholle.

The first part of the report deals with the dimensions and thread of the screw employed for attaching the camera to the tripod, but as the details suggested are still to be discussed, it is scarcely worth while to go into them prematurely. With regard to lenses, after mentioning the various modifications that have been proposed in connexion with flanges, mounts, and fronts, the report states that the Committee have decided to recommend a series of standard flanges, the diameter and threads of which are mentioned, but need not be discussed here. A system of adapters is also suggested for existing lenses—in fact the proposals are, in a general way, identical with those of the Photographic Society of Great Britain, and it only remains to be seen whether the details will agree.

In connexion with camera fronts, it is also proposed that these be made subject to some definite rules; that they be made square and without rebates, so as to be interchangeable from one camera to another, and that, like the flanges, they may be constructed of standard dimensions.

Concerning the question of "Uniformity in the dimensions of plates," it is proposed to adopt sizes whose dimensions are 3 : 4, these shapes being considered the most generally useful and pleasing. Nothing, however, is said with regard to the adoption of any international standard of measurement, which seems to be the greatest difficulty.

The seventh and eighth questions fall to the lot of M. Leon Vidal to report upon and deal respectively with—"Uniformity in the expression of photographic formulæ," and "Uniformity in the denominations of photographic processes." In the first case, the question of a uniform system of weights and measures is, of course, mentioned, but no definite proposition made beyond the suggestion that, in all formulæ, "solids shall be expressed by weight and liquids by volume." With regard to nomenclature, it is proposed, "especially in photographic works and catalogues," that "chemical terms be employed in place of the abbreviations which constitute purely a studio jargon."

Turning to processes, it is to be attempted to establish a definite system of terminology, in order to distinguish and describe different processes. Thus "type" and "typie" are to be confined to processes for the production of relief blocks, while "graphic" is to be confined to the description of such processes as "photo-cellographic," photo-lithographic, "photo-zincographic," &c. "Photogravure" is to be divided into *en creux* and *en relief*, to distinguish the two methods, but "helio," as a prefix, is to disappear, as being an unsuitable adjunct to the name of a process in which the *sun's* light may be, and generally is, dispensed with. "Platinotypie" "autotypie," "collotypie," "phototypie," and a host of similar names, are to be suppressed.

The ninth question, "Custom House formalities for the circulation of sensitive preparations," is treated by M. Bordet.

The Committee, in this case, content themselves with expressing a wish that in all countries a dark room may be provided at every Custom House, in which packages containing sensitive materials may be opened, and, further to facilitate the passage of such goods through the Customs, that senders will make them readily recognisable by means of a distinctive label bearing inscriptions in the language of the sender as well as of the receiver.

The last subject for discussion is the "protection of the artistic property in photographic works," and the report is from the pen of M. Perrot de Chaumeux, himself a lawyer, who sums up the conclusions of the special committee in terms of which the following is an abridgment.

The Congress expresses a wish that photographs will be protected by the same laws as those which protect artistic property. Among the special questions to be submitted will be the ownership of the negative. Is it the photographer or the sitter who can claim it? The Committee have unanimously adopted the view that, failing other special agreement, the negative belongs to the photographer. In the case of a portrait, the sitter, or his representative, possesses the right to "the image," and the photographer remains proprietor of the negative. The sitter cannot compel the photographer to deliver up the negative, no matter what price may be offered, but may demand its destruction upon payment of an indemnity.

It has been unanimously decided that the words, "The sitter is proprietor of the image," signify that the photographer cannot print any proof of the negative without the consent of the sitter or party concerned. The same rule will apply to all photographs ordered.

With regard to the right of reproduction, the Congress will propose the following resolutions: Every photographer who shall desire to retain the exclusive right of reproduction of his work will be required to register it. Each photograph, in such case, must bear the name and address of the photographer, or the imprint of the publisher, and, in addition, the announcement "Registered" (*Deposé*). Every photograph sold, or offered for sale, without these formalities having been complied with, becomes public property (*tombe dans le domaine public*), except so far as regards the right of third parties.

Our *resumé* of the various reports has occupied so much space that we must reserve our own comments until next week.

NEGLECTED PROCESSES.—THE POWDER PROCESS.

The powder process, or as it is frequently termed the "dusting-on process," is one that has numerous useful applications, for there is scarcely any department of photography in which it may not be made available. Why this process should be such a neglected one, seeing how useful it may be, is a matter of surprise to many. Although its actual employment is limited, it cannot be classed as an obsolete process, for every now and again some new adaptation of it is being brought forward. Still the fact remains that, in this country at least, it is not at the present time, nor ever has been, worked to any very material extent.

Quite recently, however, the oldest application of the dusting-on or powder process has formed the subject of a patent, and was demonstrated in London before the non-technical press a short time back as a new invention. The "new invention" in this instance is for the production of pictures on ceramic ware. Curiously enough, the first practical application of the

process was for the same thing. Many of our older friends will remember the burnt-in pictures shown by M. Joubert, then of Porchester Terrace, when he read a paper before the Photographic Society, so long ago as the year 1862, on the process for which he had taken out a patent a couple of years previously. Obernetter, in 1864, also patented an application of the dusting-on process for ceramic work.

The powder process consists essentially in coating a glass or other surface with albumen, gum, dextrine, sugar, or analogous substance, mixed with a hygroscopic one, such as honey, glucose, glycerine, or similar compounds, together with an alkaline bichromate. The principle of the process is this: The action of light hardens the film, while those portions which are protected from it remain more or less "tacky," according to the protection afforded by the *cliché*. After the exposure, pigment in a fine state of division is dusted over the film and gently manipulated with a soft camel-hair brush, when the powder adheres to the tacky portions and is rejected by the hardened ones.

From the above brief outline of the process it will be seen that, to obtain a positive image, a transparency must be employed, while for a negative one a negative is necessary. The results obtainable by this process are exceeding fine, while of course any pigment—vitreous or otherwise—can be used. In fact, any material in the form of an impalpable powder is equally available.

Somewhere about twenty years ago the late Mr. Window worked the powder process, commercially, as a means of obtaining carbon pictures on canvas, so as to avoid the intervening layer of gelatine—always an element of suspicion in oil paintings. The same gentleman also patented an application of the dusting-on process to photo-lithography. In this case the powder used was powdered resin, and, after the image was obtained, it was rolled in contact with a heated lithographic stone, upon which it "set off." The principal use to which the process has been put commercially is, perhaps, in the production of burnt-in photographs on enamels, but here, of course, its application is the same as for porcelain. In this direction, however, it is now largely superseded by the substitution process, which is said to yield results possessing greater vigour, unless the image is afterwards reinforced by hand work.

Mr. Cowan, Mr. Faulkner, and others have employed the dusting-on process, commercially, for producing pictures on opal glass. For this work it is eminently adapted, inasmuch as there is great scope for producing a variety of effects, as the pigments can be applied locally, and only where they are required. Therefore, better results in many ways—in vignetting, for example—can be obtained than by any of the other methods of making "porcelains." Of course any colour pigment can be used, and its tint may be further modified by the local application of one of another hue. Some years ago Mr. Werge published a method of introducing backgrounds into negatives by the powder process, and produced some excellent results by its aid.

For the improvement of negatives the process is of great value. The method of using it in this direction has frequently been referred to in back volumes. With it we have often converted into good printing negatives those which were so thin that they would not yield to any other method of intensification. The method is this: The back of the negative is coated with the sensitive mixture and exposed to light through the front; then the powder—in this case plumbago—is applied in the ordinary

manner, so that, in the end, a second negative is obtained on the back of the original one. And, what is more, as the plumbago can be applied locally, we have the means of increasing the density in certain portions, while others, if necessary, may be left untouched.

One of the most useful purposes of the powder process is in the reproduction of negatives which are required to be reversed, as they are in several of the photo-mechanical processes. Here we have the means of obtaining just what is wanted, direct in one operation, without the intervention of a transparency, so that the utmost possible sharpness, so essential in these processes, is secured.

Ere this, many of our younger readers have doubtless exclaimed, If the powder process is such a valuable one, and its applications so multitudinous, how is it that it is so little practised? Well, there is a little difficulty in the way, except, perhaps, for small sizes, and that is in the ever-varying climate of this country. As the process is dependent upon the hygroscopic condition of the film, it follows that its composition and the manipulations have to be modified to suit the prevailing humidity of the atmosphere at the time of working. Conditions which would yield excellent results one day, when the atmosphere is dry, would totally fail on the next, if it happened to be damp and humid. Nevertheless, when these conditions are thoroughly understood and compensated for, there is no difficulty whatever in the process.

WE understand that the Jurors of the Photographic Section at the Paris Exhibition, of which Mr. W. England was chosen Vice-President, are getting near to the end of their duties. The task of examining the exhibits has been very heavy, as the exhibitors in the French section alone are nearly 300, and added to these are those of foreign countries and the French colonies, therefore our readers may form some idea of the amount of work the Jurors have had to do, and which has employed them several weeks. However, as a little relaxation to their labours, they have had invitations to the President and to the British Embassy, and no end of dinners, and a special invitation to Jurors only was given to a programme at the opera. We may add that we have every reason to believe that the British exhibitors will have every reason to be quite satisfied with the awards, which will soon be published.

WHO, among all the British dames, would behave as nobly as Miss C. W. Bruce, of New York, has done in the interests of science? This lady has presented a sum of over ten thousand pounds for a telescope and appliances to be exclusively devoted to the photography of the heavens at the Harvard University, Boston, U.S.A. Such generosity deserves to be placed on record in every place throughout the globe.

THE employment of chlorophyll for the production of colour sensitive-ness in gelatine plates has been thoroughly worked out by Mr. Ives, who recommends the leaves of blue myrtle as a source of this chemical. It is unfortunate for the use of this particular colour sensitiser that it is of rather indefinite nature, authorities being divided upon its preparation, its properties, its composition, and, indeed, as to what should properly be included under the term. In a recently published treatise by Dr. E. Schunck, he looks upon it almost as do Messrs. Oelletier and Caventon, as "simply the substance, or, it may be, the mixture of substances, to which the green colour of ordinary healthy leaves and other vegetable organs is due."

OUR chemist obtains his chlorophyll in a particular method, which Dr. Schunck condemns, seeing that it is readily soluble in water; indeed,

he believes that it has not yet been obtained in a state of purity, the method, by the aid of alkalis, for example, giving a substance which is rather a modified chlorophyll. His process for making an approximately pure solution is fairly simple. He mixes alcoholic extract of grass with twice its volume of water and agitates with ether. The ether takes up chlorophyll (and other substances) and leaves certain yellow colouring matters behind. The indications of its solutions under spectroscopic examination are very interesting. Like the more familiar eosin compounds, they are fluorescent, and it may be noted that the writer of the treatise believes that the bands of absorption at the blue end of the spectrum shown by chlorophyll solution are due not to that body, but to some other substance. The whole work is very interesting, and deserving of attentive examination by all who take any interest in such topics.

It is remarkable that so little interest is taken at the present time by photographers generally in the subject of orthochromatic plates, the fitful zeal in experimenting that characterised photographic literature a year ago being apparently quite exhausted. And yet good, substantial work is undoubtedly being done in many directions. Quite recently our transatlantic contemporary, the *Photographic Times*, called attention to the work done in New York in this direction. As in this country, ready prepared plates are to be bought, but more particularly is attention drawn to the employment of azaline, which is not a particular chemical compound, but a mixture of cyanine and ehinoline red. It is stated that this sensitiser is used by Mr. Kurtz in his extensive reproduction establishment, and that the results are most successful, embracing the correct rendering not only of green in its various shades, but of scarlet, crimson, and even the pigment vermilion in true value.

THE use of compressed oxygen has almost revolutionised magic-lantern work, so useful and handy are the cylinders over the familiar, cumbersome gas bags. To the successful working of the Messrs. Brin's process of preparing oxygen much of this is due, and every development in the direction of improving the manufacture, and so cheapening the product, is to be welcomed. Mr. Arthur Brin has lately patented a new piece of apparatus—a rotary retort of special construction—which he anticipates will greatly improve the manner of production so as to obtain the largest amount of oxygen in the least time, and with the least expenditure of mechanical work.

WE have not yet arrived at the time when oxygen is laid on from the main, like coal gas, for illuminating, though it was promised some time ago by some sanguine inventors that very shortly oxygen should be so laid on, and at as cheap a rate as coal gas. But even apart from such luxuries of science as oxygen turned on at will from a tap, it cannot be doubted that the further cheapening of oxygen would be likely to thoroughly revolutionise existing systems of illumination in the studio. Coal gas alone has been tried and abandoned; every one can gauge the capabilities of magnesium; but an oxyhydrogen light, even by the aid of cylinders, ought to be able to be so utilised as to become a thoroughly efficient and cheap method of "lighting" the sitter. If a suitable system were devised, and the best burner adopted to give a light both strong and actinic, it is very probable that electricity would be "played out," so cheap would a light thus produced be found in comparison with the cost of working a dynamo.

HOUSE agents and others who utilise photography for advertising purposes are evidently becoming fully alive to the fact that prints on albumenised paper cannot be relied upon for permanence in exposed situations. Hence many, as their windows and different railway stations testify, are now having their work executed in platinotype, or on bromide paper. They also find it is to their advantage, as we recommended years ago, to secure pictures of a more artistic character than they did formerly. A well-lighted picture taken from a well-chosen point of view produces a far more favourable idea of a house or an estate than does a haphazard photograph taken, often, under adverse conditions.

FOR rapidity of production photo-mechanical processes have a keen competitor in gelatino-bromide paper. Here is an example. A thousand portraits from one negative were required in twenty-four hours. The order was accepted, completed, and delivered within the prescribed time. The prints were uniform and excellent in quality, and a far larger number could have been supplied if required. By what mechanical process could a like number of prints be obtained in the time, may we ask? In all mechanical processes a printing plate or mould has first to be made, and this often entails the reproduction of the negative. With bromide paper, however, the prints are printed direct from the original negative by artificial light, at the rate of two or three hundred an hour.

WHEN the weather forecast for the day prognosticates "thunder locally," some fine cloud effects may generally be anticipated. This has been well exemplified on several occasions lately. Last week there were some glorious masses of heavy clouds about with a strong sun shining behind them, giving some portions the brilliancy of molten silver. Excellent studies might have been secured in most parts. Such cloud effects as those alluded to are only useful as studies of clouds, and are not suitable for printing into ordinary landscapes. They may, however, frequently be employed in seascapes with excellent effect, particularly when the waves are in a somewhat turbulent condition.

How very unseasonable often are the specimens shown in photographic show cases. At the present time every person one meets is clad in light summer attire, yet in a large proportion of the pictures exhibited in show cases the sitters are in winter costume. Portraits of ladies in furs, velvets, and other heavy clothing, look as much out of season during the dog days as do muslins and summer garments at Christmas.

ON THINGS IN GENERAL.

OH, sulphite of soda! how many sins are committed in thy name? Such was the thought that passed through my mind when in "Foreign Notes and News" I read that Herr Paul Baktin recommends, in reply to numerous inquiries, the following formula for concentrated hydroquinone:—

"In 500 c.m. of water, warmed in a flask sufficiently large to allow of a convenient shaking, are dissolved 200 grammes, chemically pure, sodium sulphite, &c."

Now, not to dwell on the fact that a flask thin enough to allow of being heated is about the last thing in the world to drop crystals into without risk of a smash, which catastrophe, failing the placing of crystals within it, would be almost sure to follow the slacking of crystals, I should like to know what would be the value of a solution so made! Sulphite of soda dissolved in little more than twice its own weight of water! This is possible in hot water, but when the solution cooled, crystals would be found to fall out in large quantities. This is not the first time by many that this absurdity has been recommended: I trust we may have seen the last of it, but I felt I must protest. Sulphite of soda softens the film, hardens it; slows the development, accelerates it; does not do the negative one bit of good, is invaluable for the production of first-class results; the commercial salt will answer perfectly, none but the purest should be employed: and so on, *ad nauseam*, are we told and contradicted by a lot of formula mongers who neither know anything about the substance itself nor have any experience of its use. Even metabisulphite—what a pretty name!—where do we find it in chemical literature? Will some one please tell me of his own knowledge and practical experience whether, if he were supplied with a solution of this salt and another solution made by dissolving a mixture of the salts commonly known as sulphite and bisulphite of soda, he could tell one from the other by any observation of its action in a developer? I don't know if I possess a special infirmity of temper, but I do always feel angry when I see these impossible feats of solution mentioned.

The meeting of the Parent Society last week was rather interesting, the subject of ownership of negatives again coming to the fore.

Personally, I cannot see any possible stand being made for the morality of the claim for the sitter to have possession of it; if it be admitted that when a sitter previous to sitting announced his intention of claiming the negative to be made, he would be uniformly told that an extra charge would be made in that case. Leaving this point for decision as a matter of polemics, I commend to every one taking an interest in the topic Mr. Debenham's pithy statement of the case: it embraces the whole point in discussion, and gives in a few words a logically and morally correct position to take with regard to the subject—"The property in the negative was the photographer's, but the right to use it was joint." If these words were placed upon every picture sent out their justice would be self-evident, the public would see the real rights of the artist and would not be afraid of undue advantage being taken of them.

At the same meeting, too, the objections to the French sizes selected for presentation to the Congress of Photographers as a topic of discussion must be felt to be quite just; the nearer they are to square the better, for though it is easy enough to trim a print to size when it is almost as broad as long, there are occasions when a narrow plate would be actually useless through its failing to include a particular portion of the subject. Let us turn to the catalogues of the fine-art material dealers, and look at the sizes of canvases on stretchers: we find almost all proportions set with a leading distinction between the so-called portrait and landscape sizes, the latter being the narrower in proportion to length than the portrait sizes. The moral to be drawn from this is to adopt a proportion that will cut to any size, such an one, for example, as 12×18 being very unreasonable. The plan of having two sets, a broad and a narrow, would lead to too much variety. Let prints be cut exactly to a size that suits them, but keep the negative sizes as few as possible.

The eternal ten per cent. question is cropping up again, and once more a new rendering is given, Mr. Haddon recommending that an ounce of the required substance should be dissolved and the bulk made up to measure 4375 minims, that is to say, a little under nine fluid ounces. This is confusion worse confounded, and is ten per cent. in no way. If any one wishes to compound a ten per cent. solution—I suppose there are such brave men still living—my recommendation would be to dissolve one ounce of the required substance and make up the bulk to ten (not nine) fluid ounces. Then, if an ounce of the substance was needed ten ounces of the solution would be measured; if half an ounce were required, ten half ounces—i.e., five ounces—would be measured, and so on. Contrariwise, whatever number of measured ounces was taken would contain one-tenth of that number of ounces of the substance dissolved. But, as Mr. Bolas very properly observed, a decimal system is very bad, one of the worst for weighing out quantities. Unfortunately, it has seized hold of the scientific mind, and it looks as though in the end every one would have to bow down to it—for a time. "For a time" I say advisedly, as I hold a very strong opinion indeed that both decimal and metrical systems are a complete mistake for practical use; they are cumbersome, awkward, and incapable of neat and expeditious expression in practical operations. What a nice difficulty we are building up for our descendants in the distant future, who when they build up a new and practically useful system will wonder how their forefathers with a duodecimal system partly in use could with open eyes adopt so awkward a mode of measuring as doing it by tens!

FREE LANCE.

ON THE COMPARATIVE VALUES OF IMPRESSIONS FROM WOOD-BLOCKS, STEREOTYPES, AND ELECTROTYPES, FOR REPRODUCTION BY PHOTOGRAPHY.

[A Communication to the Photographic Club.]

MR. FOXLEE having at the last meeting stated that he had been successful in getting, with the requisite degree of sharpness, photographs from woodcuts in the earlier numbers of *Punch*, and referring to me as being able to furnish some particulars in respect of engraving upon wood, I felt, on the spur of the moment, somewhat embarrassed how to treat the subject without too much diverging from the point in discussion, which I take to be the most successful means of obtaining by photography duplicate copies, with equal clearness of line, of the originals from the line engravings of the present day.

Now it seemed to me, being acquainted with the changes that have taken place in the reproduction of duplicates from wood-blocks, that

the original question was still in abeyance, for, although Mr. Foxlee may have been successful in the instance mentioned, at a time when the illustrations were printed direct from the woodcuts, it was inapplicable in this respect—that at the present day electrotypes of engravings upon wood are used and not the woodcuts themselves, which are carefully stored away until the wear of the electrotypes necessitates a fresh re-casting, thus ensuring a clear impression of the illustration as occasion may require. Engravers allow that sharpness of line is most perfectly given by the lines engraved in relief upon boxwood, and that it allows of greater brightness and depths in the blacks; implying, of course, direct contact with the material upon which they are impressed—the paper.

Like other descriptions of engraving, although a large number of impressions could be taken from the wood-block, it had necessarily a limit from the wear exerted on the lines by the repeated press upon its surface serving to thicken the lines, and so render the cut useless. When such was the case—I am now speaking of its earlier history—it became necessary for a fresh drawing to be made, and the whole subject re-engraved. If not too much worn, and rescued in time, a facsimile could be obtained, and a saving of expense effected by a transfer taken in the following manner:—The block having been carefully washed and cleaned, it was again charged with ink, and a proof impression taken from it. So far, it was done with. A boxwood block of the same size was then procured, the face of which was charged with a wash of cyanide of potassium; when it had become sufficiently dry to be only just damp, the proof impression was laid upon it, over which was laid a thin piece of millboard, and the impression rubbed down upon the surface by the aid of a burnisher. It was then placed in the hands of the engraver, who was thus enabled to engrave it facsimile—line for line. Much about this time came the several inventions to improve upon the art, all of them mechanical, and all, from a certain mealiness or rottenness of line, failing ignominiously. Then came the first important change—the reproduction of the block by the stereotype process, and afterwards the electrotypes process. The first required careful examination from the frequency of microscopical air bubbles between the lines, which had to be cleared away by use of the graver; the latter process was free from this objection, and for the better class of illustrations has entirely superseded the other. [Some woodcuts were then passed round with direct impressions, illustrating the superiority in fineness and solidity of line of a direct impression from the wood.]

WALTER RAY WOODS.

PHOTOGRAPHING INTERIORS.

THE great difficulty encountered in the photographing of interiors by daylight is in the securing of harmonious illumination: certain portions adjacent to the strong light streaming in from windows opening on the street or courtyard receive the allopathic dose of light, while others get the homœopathic thousandth dilution.

I say nothing about the windows themselves, since photographers who have had much experience can alone do justice in the denunciation of the great enemy of interior photography—halation. I know all about the various devices which have been suggested to overcome both irregular illumination and halation, but these remedies demand the wholesale sacrifice of light—just what is needed most of all in an interior—and the consequent loss of time, the greatest count to the practical photographer. Good exposure on interiors with daylight is often out of the question if one wishes to have a soft, pleasing picture; but thanks to the march of improvement we are independent of the sunlight, who never seemed to care to work for us satisfactorily when we wanted him to come in out of doors and scour around the corners of dark rooms. Since the introduction of the new magnesium light it is possible to shut up all the windows and yet produce results quite equal, and in many cases far superior, to anything obtained by daylight. Minutes, or rather seconds, will now do better work than formerly was secured by exposure of hours' duration.

I remember in the days of wet photography being sent to photograph an exhibit at the Centennial Exposition. After preparing the special collodion necessary for long exposures, that is, treating it to as much water, drop at a time, as it would carry, I coated a plate therewith, and started for the scene of action. The situation of the exhibit was in a rather dark corner, and I calculated that it would take at least an exposure of half an hour. My camera was set up—not a very easy task (a 20×24 size)—the focusing accomplished by mounting a step-ladder, the holder placed in position, and the slide drawn. I now determined, while the chemicals and the lazy light were doing the work, that I might rest from my labours and let my works follow me, the time being near the close of a warm summer day. Either monotony of the exhibit (piles of chesses, arranged by some æsthetic

eye in columns and arches) or the odour arising therefrom, or weariness, or all combined, caused me to fall into a peaceful doze. How far I had travelled in the land of dreams I know not; all I knew at the time was the call to consciousness by the rough salute of the guard, that closing time had come, and the certain feeling that my exposure was either ruined by over time or the drying of the collodion film.

My traps were soon in order, and my march made double quick for the dark room. Thanks, this time, to the slow light and the slow plate, I found I had a most beautiful negative, only regretting that *technique* had not expended itself upon something more beautiful. Had I possessed the means at present so abundant for securing exposures in dark corners, I might have made my exposure and afterwards taken "my rest at my ease in my inn."

The facility with which exposures on interiors may be made with magnesium light ought to make it more popular with practical photographers, but they seem to have such an enormous share of conservatism that they are afraid of anything championed by the enterprising amateurs. The only objection to magnesium is in the fumes; but these are not serious, and the householder seldom or never objects. Pure magnesium in powder may be used, or the flash-light compounds. The latter have the advantage of accomplishing the work in a much shorter time, a fraction of a second being sufficient to secure a beautifully exposed negative with a single charge of powder. Generally, when pure magnesium is used, two or more charges are necessary, and, of course, it would be impossible to secure figures in the picture without showing signs of motion.

The addition of figures adds very much to the life and beauty of photographs. A domestic scene, consisting of the family at their usual pleasures or tasks, takes away the idea of desolation which the average interior picture conveys.

It is true that several simultaneous charges of pure magnesium could be ignited in different parts of the room and so augment the quantity of actinic influence, but the conflicting shadows so produced, cross-shadows as they are called, give a very unpleasant, not to say unnatural appearance to the picture. So I generally make use of the blitz-pulver compound, which requires less material and is more brilliant, though more noisy in its work.

It requires some judgment in determining where to locate the source of illumination so as to properly light up the objects and to cast the shadows in the right direction. I have found it advantageous to place the source of light rather high up, so as to avoid the formation of lengthened shadows on the floor.

Care must be taken that the flash is not so placed as to cause violent reflection from polished objects, and special precaution observed to keep mirrors from reflecting the light into the lens. The reflections from china and glass are most beautifully rendered by the magnesium flash, and if the source of illumination is properly managed, the reflection in the mirrors of the objects in the room adds much to the effect.

By the use of the magnesium light it is possible to obtain in the picture the view of other rooms through doorways, &c. Vista after vista may be secured with very little additional trouble. An exposure is first made upon the principal room, the cap placed on the lens, and a smaller diaphragm used to secure the proper definition in the outer room; the cap is then removed, and a charge of powder ignited in a part of the outer room where the light will not flash in the lens. In this way several exposures may be made upon the same plate.

I have obtained some very pretty effects by first securing views out of the window of the surrounding landscape, with hills, fields, and cottages, then drawing the curtain and exposing the room by means of a flash. Of course, a very small stop is used in getting the landscape, so care must be taken to remove this and to substitute a larger one when exposing for the interior.

The lens I employ is a Ross portable symmetrical, a most excellent instrument for interior work, and especially for flash-light interiors, combining considerable angle with great rapidity and perfect definition.

Some difficulty will be encountered in focussing interiors by reason of the faint illumination. I always make use of a candle to illuminate a printed page of a book or newspaper. By getting the type sharply defined, I am sure that the objects in its plane are also sharp. The lighted candle is also very useful in determining the limits of the picture; by moving it to the right and left it is easy to see just where your picture stops. I also have an assistant move it along the base line of my picture on the ground glass, and when it moves along without any eclipse I am sure that nothing in my foreground will come too obtrusively into the view. When the image of the candle disappears, I know that some object is in front which ought not to be there, so its removal is at once effected.

A word about the groups in a picture of a room. The figures should always be so arranged that the impression is given of life and animation. All set-posing, as if the people were lay figures, must be avoided.

The figures are best arranged in groups of two or three, as if engaged in conversation, or occupied with some amusement. In this way I have disposed of ten or a dozen people in one view, and the effect is much more pleasant and picturesque than when the arrangement is in the form of a pyramid, or any other set artistic disposal. W. R.

—*American Journal of Photography.*

ON THE DETERIORATION OF DRY PLATES.

I.

THERE can be no question about the fact that much, if not, indeed, the entire popularity which now attends the practice of photography by so many ladies and gentlemen is due to the advent of the dry plate, and much of this popularity depends on the belief that any one can proceed to a dealer and there procure a stock of some favourite brand of plates they have been recommended to use, which will keep either before or after exposure for any length of time, provided certain due precautions be observed, such as exempting them from damp, certain fumes of sewer or other gases, light, &c.

But is it the case that a gelatine plate, no matter how carefully stored or placed away, will keep indefinitely? Such a question as this, I feel, must be of considerable interest to the vast army of amateurs who now look upon photography as a balm for no end of business worries, and also one of the most tangible and pleasant occupations they can engage in. I therefore propose to relate a few of my experiences.

So far back as the spring of the year 1880 I determined to set about investigating this subject, and with a view of coming to no sudden or rash opinion. I commenced the inquiry by placing away several brands of plates under varying conditions of packing. From time to time I used up these different plates, at the same time closely observing their behaviour under varying circumstances. At the present moment I have beside me plates I acquired so far back as 1881, and this week I have been using some I bought in 1884.

I am aware that this subject opens up a wide field for thought, and that closely allied with the matter in consideration is the question of packing, and, as I sometimes also think, the unpacking. For with most amateurs (not so much as with professionals) the breaking into a fresh box or package of plates means very frequently the bundling up of a portion of them again, either with the same wrappers, or it may be filling a set of slides, and there allowing the plates to remain for an indefinite period. Or it may be that with some workers the belief prevails that when a fresh box of plates is opened the best means to employ is to place those not required at the time into some grooved box.

During the course of the last nine years I have studied carefully the behaviour of numerous plates so stowed away, and at last I have formed a pretty strong opinion that the best way for an amateur to keep odd lots of plates is by placing them face to face, and putting them into a metal box of such dimensions that they do not move about when same is lifted or used. I have long given over the use of grooved boxes for stowing away plates, but on this point I may have more to say later on.

From about the years 1880 to 1882 I must confess having a decided opinion that, under careful keeping, a gelatine dry plate would respond to and yield a good negative at any time after long keeping, and I was strengthened in this belief by a series of tests which I applied to a number of Wratten's plates, ranging from 1880 to 1885. In the month of June, 1880, I acquired from a dealer in Glasgow three dozen $7\frac{1}{2} \times 4\frac{1}{2}$ Wratten's plates, two dozen of these were ordinary, or, as some term them, slow plates, the other dozen were what were then and now termed instantaneous.

The first portion of this parcel which I determined to try was the slow plates, these were exposed at the time and yielded splendid negatives. The remaining box I placed away unbroken, and never touched them till the month of May, 1886. This box was placed inside a wooden box in my dark room, and was frequently handled and tumbled about during the years between 1880 and 1886, but not opened. In May, 1886, I determined to put to the test the keeping qualities of these plates, and proceeded to expose two of them on a well-lit landscape (time, 6 p.m.), with plenty of low shadows; at the time I exposed on the same view a plate from an ammonia formula which I had kept from September, 1884. I developed them with the

same developing solution, namely, Wratten's formula. Result: the slow landscape of Wratten's came out most beautifully, yielding one of the best negatives I have in my collection, while, on the other hand, the ammonia plate fogged up and was utterly worthless.

The remaining ten of these plates I placed away face to face in a metal box, which was stowed inside another white wood box, and last year I used these up with equally satisfactory results.

So much for the slow landscape plates. Now as to the behaviour of the instantaneous ones.

The first portion of these I placed in my slides (six plates), and proceeded in the month of July, 1884, to expose some of same on steamers calling at Craigmore Pier. Three of these plates were exposed in good light on the pier. I used stop; I think it was about $f/10$, at any rate it was the widest stop that Ross at that time issued with his rapid symmetricals, and before the introduction of the new series of standard stops. On development I judged the plates somewhat under exposed, and on forcing up I got a fair dose of green fog. The remaining three plates were taken out of the slides and placed away in a mahogany grooved box along with a few other ammonia plates which I placed in the box along with them.

I find from my jottings that I exposed two of these (Wratten's) in May, 1885, with the same result—green fog on development. The remaining seven plates I have beside me still, and shall proceed to test them with a different developer very shortly.

Now, during the years 1880 to 1882, I used many gross of Wratten's instantaneous plates and got uniformly good results therefrom. Many of these plates I must have had beside me from one season to another, hence my forming the opinion that a gelatine plate under certain conditions of storing would keep almost indefinitely.

With the introduction, however, of plates of more exalted sensitiveness, I soon found a change coming over the spirit of my dream, and in 1884 I came to the conclusion that several brands of plates which were then being placed in the market would not stand on the same footing as regards keeping with those which the public had first offered to them.

About this time I became connected with a plate-making company, and I had through this circumstance, perhaps, as good an opportunity as any one of forming an opinion as to the merits of a boiled *vernus* ammonia emulsion. It will not be telling tales out of school when I say that I soon came to the conclusion that an ammonia plate would not keep for any length of time, either in a packed or unpacked state. I must, however, confess that perhaps the best negative I have in my collection is one made on a plate coated with an ammonia emulsion, but this plate has a history which were I to relate might interest many.

Being a Director of a Dry Plate Company, I was asked one day by the manager to accompany him in testing a fresh batch of plates coated with an emulsion that he had specially prepared for a large firm of photographers.

I remember well taking my empty slides and having them filled direct from the drying cupboard; a few hours later on these plates were exposed; results, splendid. Several of these negatives have been a joy to me ever since. Now, being so satisfied with the results, I at once got a supply of plates from this same batch. Knowing the emulsion was A1, judge of my surprise when not very long afterwards, I don't think it was beyond six weeks, I was startled with nothing but absolute failure when exposing some of what were said to be the same batch. I found these plates to yield nothing but fog and black edges. I took care to make inquiries as to their being from the same batch, and have every reason to believe such was the case.

I tried to account for the breakdown by some action of my own, but failed to account for the rapid deterioration in any way.

So much for tests applied by me to Wratten's and a plate by another maker, which I have termed an ammonia plate.

In September, 1883, I determined to make further tests by placing away some 5x4 Gray's plates; these I placed in their regular boxes and wrappers, and they lay quite undisturbed in a parlour cupboard, which is quite free from damp, until last week, when, cogitating over this article, I determined to put them to the test of time. I was most agreeably surprised to find them develop up with Wratten's ammonia formula into fine bright negatives. Not so with a supply of Bennett's plates, which I have kept from, I think, early in 1881; the latter on development gave signs of insensitiveness, and would stand no degree of forcing.

At present I have beside me a supply of Nelson's plates which date from 1882 to 1883; they are untouched, and packed as they left the works in wooden boxes. In the course of a day or so I mean to place these along with a supply of ammonia plates made by a local maker to a fair test side by side, and in my next I hope to give results of the

same, and also to detail in a somewhat full manner the deterioration a plate is likely to show by careless packing or keeping after being opened to the influence of the atmosphere. T. N. ARMSTRONG.

COLOURED PHOTOGRAPHS.

IV.

NOTWITHSTANDING the beauty and excellence of so many of the photographs produced by our leading photographers, I think we must all concede that as *correct portraits* they are in many and very remarkable cases defective. By this I wish to say that a *plain* photograph (even aided by the skilful and artistic retoucher) may be perfect in all its mechanical and chemical details and yet be wanting in that strong resemblance to nature which is absolutely essential in order to make it a life-like portrait. The cure for this trouble is to be able to skilfully and artistically apply colour to it. This done successfully a life-like portrait will result.

I am sure all those who have practised photography for any time will easily recognise the truth of all this; who, with any lengthened experience, will not have had to operate upon subjects, that, owing to the chemical peculiarities of photography, cannot be rendered in any form which pretends to truthfulness, and will never be faithful portraits until they are coloured. Such pictures must ever be imperfect and untrue as depicted in the monotint of photography. A most skilful operator may have produced them, with every care and attention, artistically posing the subject, judiciously balancing the distribution of light and shade—indeed, realising what may fairly be considered a *picture* (and a successful one), yet as a *portrait* it is valueless. All this may be traceable to the chemical peculiarities of photography, but there the defects remain and no excuses can take them away. Besides, there are very many subjects that would be impossible to depict in a portrait picture without colour. Colour is an essential to them. It is their colour which first appeals to you, and must, consequently, be an all-important factor in the production of a portrait.

To colour photographs then, with any degree of success, one must have a thorough knowledge of what they are going to do. That manipulatory skill which enables one to apply colours to a photograph, with more or less success, must not be considered as sufficient for what we have before us. This might be all very well for what we may call a *tinted* photograph, but not for one that is *coloured*. To carry out my idea, therefore, that a portrait full of style and merit can be painted on photographic base, we must try to lay in a store of knowledge quite equal to the artist who might not deign to use a photographic foundation for his work. Without having a sound primary knowledge of the natural value of colours our work will always be weak as regards treatment and devoid of style. The natural weight of the photograph, too, will assert itself, and also detract from the value of the painting.

In studying the art of colouring, whether on photographic base or otherwise, our first endeavour should be to acquire a thorough knowledge of the natural value of colours, their various relations and harmonies, their many effects and balances, if I may so say, either in combination or juxtaposition. It may seem strange that, although we have a somewhat limited number of colours to start with, by their skilful combinations we can produce an almost endless variety. The *primary* colours are only *three* in number, but how many various tints can be produced by their skilful blending I cannot really say. In a picture this is not all, even; for many of its most striking beauties may not be so much the brilliancy or attractiveness of the absolute colour as the delicate harmony produced by the *combination* of such colours and tints as mutually lend a charm.

In landscape, one is more likely to observe the endless variety of colours presented to the eye than in any other form of painting; nature being, I might say, exhaustless in its variety of tints. So, too, in fanciful or imaginative portraiture one will find more varieties than in portraiture where nature pure and simple has to be imitated. I do not mean by this to say that even the human head does not possess very many and delicate colours. On the contrary, it is just in the keen appreciation of these delicate tones that an artist of more than ordinary capacity will show himself. Where a very ordinary colourist would be satisfied with a warm or pinky colour for the general tint of the skin, the skilful artist would employ a number of delicate tones to carry his colours over the head and give it life and roundness, which his less gifted rival might even fail to appreciate. Needless to say, in photographic colouring there is not such a vast range open to an artist as where he has to produce all effect himself. Nevertheless, works of very great merit can be produced, and it is

really marvellous the difference observable between the pictures produced by the common or garden photographic colourist, who has never made a study of harmonious colouring or the fundamental rules of art, &c., and those painted by an artist who keenly appreciates all the delicacies of light and shade, relief, &c., and who also benefits by the knowledge he has acquired in skilfully blending and arranging his tints in such manner as to impart a further charm to his work. Yes! the work of the one is simply valueless, while the other's may be well worthy to be considered a work of art. This, too, notwithstanding the primary help that photography has lent him.

In portraiture, as in poetry, an artist can claim a certain license, a freedom of treatment. Although there will necessarily be certain colours which *must* be faithfully reproduced, the artist can almost have *carte blanche* as to choices of colours for the draperies and backgrounds, &c. This liberty may not appear to be of any great importance to one who does not know and does not think, but all the same it is of very considerable value to the *portrait painter*. In this way he is enabled, by a skilful arrangement of colours and tints, to enhance the value and beauty of his *complexions*, and yet not in the least interfere with the general harmony of his picture. An appearance of transparency, too, may be realised which, had this liberty been denied the artist, he could not hope to secure.

Light is the source of all colour, and without it there is none naturally. A beam of pure white light can be divided into three distinct rays of different colours—red, blue, yellow—these being the three *primary colours*. By the various blendings of these three colours every conceivable hue and tone can be obtained. White light, when decomposed by passing through a prism, produces a scale of the most beautiful and varied colours; this is what is known as the *solar spectrum*. In this spectrum there are seven colours, the same as are to be seen in the rainbow—namely, violet, indigo, blue, green, yellow, orange, red. The belief at one time was—founded on this fact—that each and every one of these colours were elemental. Later and more careful examination, however, proved this theory to be a fallacy, and resulted in the establishing of red, blue, and yellow as the *real* and *only primaries*. All the other tints were simply the result of these primaries overlapping each other, and so producing a distinct colour, as would their mixing upon a pallet.

General harmony in a picture is traceable to the artist's success in happily disposing of these three primary colours and their various combinations. At the same time I may say that this quality is one of, if not absolutely the most essential one that a picture can possess.

The mixing in certain proportions of any two of the *primary* colours produces what we term a *secondary* colour. Now this secondary will be found to be *complementary* to the remaining colour. To make this clear, the mixture of *blue* and *yellow* will produce *green*, and green will be found complementary to red. The mixture of *yellow* and *red* produces *orange*, which is complementary to blue; and the mixture of *red* and *blue* produces *purple*, and which is complementary to yellow.

A very good way of fixing this on one's mind is to make a circle and divide it into six equal parts, and place a number in each up to six. This done, pass a wash of red over 1, 2, 3; when dry, pass a wash of blue over 3, 4, 5; and then yellow over 5, 6, 1. Now see what we have: a complete table, as it were, of our primary colours with their complementary secondary colours. Space 1 is coloured orange by the combination of red and yellow, that opposite to it being the primary blue, to which it is complementary. No. 3 is coloured purple by the combination of red and blue, and is opposite the primary yellow, and to which it is complementary. In like manner space 5 is coloured green by the mixture of blue and yellow, and is opposite and complementary to the remaining primary red.

Modifications of these tints may be carried on to almost any extent with similar results, and doing so even to a moderate extent will be found wonderfully effective in instructing the eye as to the harmonious placing in a picture of the various colours. The combination or mixing of two secondary colours will produce what is termed a tertiary, and which in its turn is complementary to the remaining secondary. As an example, take purple and green—olive is the result, this is complementary to orange; purple and orange produce russet, complementary to green; orange and green produce citrine, which is complementary to the remaining secondary purple; and so on to any extent.

It might be thought that the relations of these various colours and their blendings with one another are the result of taste or fancy; not so, they are based on sound art principles. They seem to exist as a physical necessity for the organs of sight, as may be seen by a very simple experiment. This was turned, some years ago, into an advertising medium by a firm of extensive advertisers. Place a red wafer

on a sheet of white paper, then fix your eyes steadily on it for some moments, then transfer your gaze to another *plain* sheet of paper, and in a couple of seconds you will, as it were, see another wafer—but of the complementary colour to red—green. This *ocular spectrum* will remain visible for a few moments, but gradually the white light reflected from the paper will completely displace it. This experiment holds good all round—a blue wafer an orange spectrum, a yellow wafer a purple one.

In the endless varieties of the various combinations of colours this principle will ever hold good. Thus, if a tint of red inclines to a yellowish hue, as in scarlet, the complementary green must have a slight preponderance of blue, and so be a bluish green. If the red partakes somewhat of the blue as in crimson, then the complementary must incline somewhat to yellow, that is, be a yellowish green. This might be carried on for ever, so numerous are the combinations and so delicate the gradations that can be so formed. To follow them in detail here would be madness, but for private practice it will be found very advantageous.

All colours, whether primary or secondary, will be found to possess certain delicate contrasts and effects quite peculiar to themselves; as, for example, blue is the coldest colour also the most retiring, while orange, its complementary, is the warmest and most assertive or advancing. Thus every combination as it approaches orange or blue will be warm or cold as the case may be. It also suggests the effect of approaching the eye or retiring from it in the picture.

Yellow is the brightest colour—the fullest of light; its complementary, purple, is the darkest. White and black, although they represent the contrast of light and darkness, are not regarded as *colours*. White, which most assimilates with light, is supposed to represent a combination of all the colours; while black, like profound darkness, is an absolute absence of both colour and light.

Red is the most positive, exciting, and aggressive of all the colours, yet its complementary, green, is the most soothing and grateful to the eye. In mixing tints it will be found that two primary colours seem to form a new and perfect hue, but every subsequent combination will tend towards neutrality. The neutral tints so formed will be found to possess the characteristics of the primaries to which they are most allied.

Contrast is produced by the skilful placing in juxtaposition of the complementary colours. They mutually benefit each other and secure *harmony* of contrast. Thus purple and yellow of equal purity and volume will each become brighter by contact—the yellow gaining intensity by the extra yellow rays reflected by the purple, and the purple additional richness from the purple rays emitted by the yellow. Similarly all neutral tints placed near full hues seem tinged with the complementary colour of such hues. A grey in close proximity with a red will seem to become a kind of greenish grey, green being the complementary of red. One can form some idea from this how important it must be to skilfully arrange these various tints so as to produce brilliancy and harmony over the entire picture.

REDMOND BARRETT.

PHOTOGRAPHY AND CRIME.

THE Police Museum, Scotland-yard, contains much of photographic interest. Its "speciality," of course, would be, and is intended to be, an exhibit of remnants (assorted) connected with bygone atrocities and cases of general interest. It well serves its purpose. The room is a very miserable one of whitewashed walls, now a dark brown, changed possibly from its former tint by its ghastly contents. To one well read in records and detailed connexions with notorious cases, this collection must prove entertaining; and to such, by all means arm yourself with an order from the Assistant-Commissioner and make tracks. The writer was pressed for time, and very mixed as to names and the particular crimes dating many years since, therefore all errors hereafter committed must not be classed "clerical errors," but attributed plump and plain to sheer ignorance of that he talks of. He right away confesses of knowing little or nothing of them. How should one who tries to avoid as far as possible papers that serve up at breakfast-time strongly coloured—not ordinary photographic black and white, but highly-coloured—details in this sort of thing? If you wish to breakfast, breakfast and enjoy it. But how was it, says the reader, you allowed your delicate organization to enter the very heart or essence of that you tried to avoid? "Well!—well, you see, such is the weakness of human nature, the most frivolous of all animal natures!"

On entering, the first little lot is that of the Wainwright case. Here you have two small portions of the murdered woman in spirits—one from the thigh, and the second a portion of bone; also the gold earrings

he wore. The chopper with which Wainwright did the crime you may handle, and it is that of the ordinary wood-chopper shape. The spade he used to dig the hole for the body is likewise here. A topper stuck on a pin is the cigar he was smoking when arrested.

Further on you find a bundle of tricks, once the property of a gentleman, or gentlemen, who thought it no harm in starting a small opposition to the Mint, by way of manufacturing two-shilling and half-crown pieces; to allow a good profit and save expense, utilised bismuth in lieu of silver as a fundamental basis. Their home-made articles appear to receive the greatest and tenderest of care, each coin having a separate wrappage of tissue paper. And so things went on with them swimmingly, until effectually stopped by a dignified high-handed official from Her Majesty's department. This set is shown under a glass case, and looks both bright and pretty. The plaster moulds contain two coins ready for disconnecting and exchanging.

Another set is that of a bundle of "Flimsies," or "Bank of Engraving" five-pound notes—stock-in-trade of those who work, and often in this nineteenth century successfully, to bring off the confidence trick.

A very handsome box in morocco leather was taken by a would-be customer to a West-end jeweller, who there rung the changes, taking that full of value and leaving behind his *facsimile* containing but two lumps of good quality Wallsend coal!—black diamonds in exchange for white.

"Charley" Peace has quite an assorted collection, including a very original portable ladder, which folds to about twelve inches, made from strips of wood; the green goggles and artificial arm stump he so delighted to use to conceal his identity; quite an artful, miniature, sharp-biting hand-vice, with which he used to nip from the outside the small protruding portion of the key left in the door-lock, showing the folly of considering oneself safe when, having locked up, you leave the key in.

Tichborne (?) is represented by a neat pocket comb in limp leather case, pencil case, and many small but useful little trinkets generally used by one particular, very, in his general get up.

Many sets of white caps and ropes, used for certain hanging jobs, are about the room, with generally a plaster cast after death of the culprit to each. There are hardly two alike in the matter of dislocation. The ropes, for substance, are much thinner than one would think. The caps fit the head awfully tight, although the cranium on which it was now tried was of small dimensions, still it came "awfully near it," and would render breathing all but impossible. It is not at all strange at an execution, after the prisoner receiving the white cap, that he says nothing further—funny if he did! He must by then be partly suffocated.

An interesting portion of the show is that which places beyond all question the value of photography. It is in connexion with the murder of a policeman at Dalston some little time since. He was shot. Behind was left only an old, soft, felt hat and a chisel. Now, this chisel was found by a photograph to contain a certain word scratched on the blade. An enlarged picture brought it out visible from the invisible. This and this alone brought about the apprehension and consequent hanging of the murderer.

Passing along you come across a big boom in an assortment of jemmies, all shapes and sizes; some roughly made, others finished with the greatest nicety. Jemmies to fold, jemmes to screw, and jemmes with bayonet joints. Some carefully packed in close-fitting green baize bags, devotedly cared for as a pet dog; others large, with ugly-looking capabilities to render a nasty knock if called upon; some small in size, but very determined in substance, while a few looking too delicate to do any mischief whatever.

Decorated on a red cloth are many pistols and revolvers; dimensions ranging from the old blunderbuss to the neat ivory handle nickle pocket piece.

A trio of snobs' tools—two lap hammers and knife, tied together by a piece of string—are those the wretched Cornwainer used to smash the head and cut the throat of a sleeping woman with whom he cohabited.

A frame of clever photographs, illustrating the "twelve types of crime," done from life, at once seize the attention. Who made them it does not say, but evidently done by one of great ability, both for artistic and technical knowledge of the art. Photographs are very prominent throughout the room, and, no doubt, a great factor in bringing about detection. Clock movements of captured infernal machines are shown in their varied positions of working.

The catalogue takes the form of a manuscript-book illustrated by photographs. Many criminals are shown; Madame Rachel, for instance, with a brief sketch of her doings, trial, and resulting term of imprisonment. In this picture she looks far from beautiful.

Quite a nice-looking, gentlemanly cabinet is that of the one who

succeeded in killing his half-brother by way of sending him sweetmeats, which also contained a small capsule of poison. He was found guilty, and paid the law's full penalty. The identical capsule is shown pinned on a card.

In a corner stands a red banner captured by the police from the mob of unemployed of Trafalgar-square fame; the catalogue describes it as the "Battle of Trafalgar." A pad and padlock with which a foolish man locked himself to the railings of St. Martin's Church, declaring the right of meeting and that he should not be moved.—He was.

A peep into the "Album Room" at once proves a great amount of busy, brisk work to be done within the prison walls. The albums are tremendous books, all loaded; many, many thousand criminals are here illustrated, all in one position generally—large bust, with the open hands flat on the breast, broken or peculiar finger-nails being thus recorded.

T. COAR.

JACK AND I IN NORWAY.

VII.—SÖHOLT, GEIRANØER FJORD, MARAK, HELLESYLT, AND GRODAAS.

THE first four miles of the journey from Vestnaes was very charming, quite like English scenery, trees, shrubs, and grass in profusion, and in the evening light everything looked placidly soft and green; but as we drove further on our way gradually we left foliage and vegetation behind, and entered on moorlands barren and bare. The withered patches of heather stood up on either side of the road, and oh! such a rough road as it was. The switchback railway was nothing to it. The willing little pony spanked along, up and down, up and down, on a perpetual series of land waves, so to speak. It was not very easy for us, for the stolecarrie was fitted with pillars round the back support, and when we came upon the rough places these pillars were rather rough upon us, for with every jolt they caught us in the back producing a sensation that was far from pleasant. It became unbearable, and we had our rugs arranged over this ornamental work in the form of a cushion, which brought a little comfort.

This drive to Söholt was the roughest ride in all our tour. The first station on the route was about ten miles on; it stood on a scraggy heath amidst oppressive loneliness. We reached it at midnight.

On our arrival two rough-looking fellows appeared from a dilapidated house and came towards us; in the sombre light they looked extremely ugly, and the surroundings were awfully chilling. The whole appearance of things did not strike us as right. The biggest of the two fellows insisted that we should have two horses, we insisted that we only wanted one, he argued that one was not fit to make the journey, the roads were so rough; with the usual assurance of ignorance we told him that he talked nonsense. He then lifted our portmanteau with seeming great difficulty to show that it was heavy. I then lifted our rugs with greater difficulty to show that they were heavier. This last trick brought a smile to his sombre face; at this he succumbed and produced his horse and stolecarrie. We felt rather uncomfortable as we proceeded on our way, for to use an Irishism, that same man was to be our boy for the remainder of the journey, and there he sat on the luggage at our backs. As we drove away imagine the scene—a stretch of miles covered with snow, with dots of heath and heathery patches, at intervals a leafless tree standing up alone with its barren branches reflected against the sky like a weird skeleton, long thin posts standing up on either side of the way to guide us in the track, frozen lakes every here and there glimmering in the midnight light, and the grating wheels of the conveyance kept grinding through the crisp hard snow—it was desolate; and, to crown all, the warm breath from the man behind played about the backs of our necks, making the situation more eerie still.

Up and up, hills over hills, until the road became too steep and heavy for the horse, and we got out and walked. On the beaten track we plodded on through slush and snow some three feet deep, hill over hill we trudged along, only to find a higher one still further on, and by the time we reached the topmost height we were quite blown; weary and breathless we sat down upon a rock to await the horse and driver—they had been left far behind. As soon as we got the turn of the hill, "a change came o'er the spirit of our dream." The man stood up on the baggage behind. With reins in hand he encouraged his pony in some unknown dialect, when it started away and down those hills like a whirlwind it sped; if we had encountered any obstruction on the way we must have gone to utter smash. Down, down, unharmed we kept our way, and with such speed that we sat motionless, looking forward in breathless suspense for miles; it seemed as if it would never end, when with a heaving sigh we cry, "At last!" as we reach the lower level, and in the early morning come upon avenues of trees, pass houses, see human beings—civilisation once more. We paid our sombre guide well, but he returned no thanks; then into the hotel and to bed, to sleep the bad impressions away.

Söholt is a bright little village abounding in a wealth of vegetation. We made use of the morning in taking some views of the place, as we had to start by boat in the forenoon for Helligslyt on the Sunelv Fjord. On this journey we again came upon ranges of mountains like perpendicular barren walls, thousands of feet high, with only a shelving of rock or a small flat covered with grass to break the monotony of these towering walls, or it

might be some little house looking no larger than a packing box with windows in it set in a most precarious position half way up to the clouds.

On the way the Captain drew our attention to some white painted squares on the rocky part of the mountains, and quite in the water. He explained that they were put there to attract the fish, who when they saw these light parts immediately made for them and thus got netted or trapped. I suppose this idea is much the same as the torchlight used to attract the fish in our spear fishing.

We did not land at Hellesylt, but went right on to Marak, passing through the Geiranger Fjord, the scenery of which is considered as fine as anything in Norway.

On the mountain top, just where we entered this fjord, there was a cap of snow looking as if it would hurl over at any moment. The Captain gave this impending mass a wide berth by sailing over under the hill on the other side, for should it happen to come down the weight of it would be hundreds of tons, and, as he sagely observed, "If we were caught in it we would go down to the bottom never to come up again."

Near this place the Captain drew my attention to one of those little wooden houses set upon a shelf of the mountain. "Do you know," said he, "that a strapping young fellow sold himself for that house up there?"

"How so?" I asked.

"Well, for the sake of that place, he married an old woman that might have been his grandmother, and there the two live together now."

"Oh, well, both the sacrifice and the gain are comparative things," I said.

"I do not understand you," replied the Captain.

"Considering the conditions, a young fellow living at any rate in such a place as this, the sacrifice of binding himself to an old woman might not be so very great, and this shanty of a house that I would not take in a gift might be looked upon by him as of considerable value." He shrugged his shoulders and laughed.

This fjord is very narrow, and as we twine in and out of a seeming land-locked watercourse, the face of the rocks take on many fantastic and grotesque shapes and forms. To the sailors who are continually passing out and fro these markings of time and weather form themselves into pictures of men and things, and a lively interest is kept up in pointing them out to the stranger, to see if he also could trace the likenesses that they have formed on the surface of the rocks. We were shown men's faces in jagged profiles, wonderfully good; and before coming to the Seven Sisters Fall, but on the other side of the fjord, the Captain pointed out to me what he called the minister in the pulpit, and when told what to look for it was really very like. The tracing and carving on the front of the pulpit, with the place for the book and the minister behind, all came out quite clear and distinct. Now this must have grown out of the fancy of some one, who, when gazing upon the worn and furrowed rocks had been tricked into the fantastic resemblance, like a child seeing pictures in the fire.

The Seven Sisters is a celebrated series of falls close together in this fjord, but on our way to Marak the light was dead against us, and we could not get a picture of it then; but as we had to return the next day at a time when the light suited, the Captain promised to stop the boat there and thus give us a chance of taking the falls.

As we sailed into the bay at Marak, the valleys looked very inviting, lying bathed in the light of the evening sun. There were a good few people on the boat, and by the time that we saw to our traps and reached the hotel we found that it was crowded, but we got quarters in a new house further up the hill belonging to the hotel people, and which they kept as a reserve for the press in the summer months. We were very comfortable here.

The whole place is small, built on the face of a hill, the houses zig-zagging down from the highest point to the water much in the form of a Z. We only stayed one night at Marak, and went through the Geiranger Fjord again next day, but for a tourist photographer with unlimited time on his hands, Marak would prove a good centre for camera work, as interesting rivers, falls, mountains, bridges, and glaciers are to be found within easy distance of it. We took impressions of the village from the bay.

On our way back the Captain was as good as his word and stopped the steamer just before we reached the Seven Sisters Fall, and we made two exposures. This fall is so named from the fact that seven falls in close proximity to each other come lashing down from the mountain top. Two of these had dried up when we were there and only five were on the fall, the Captain playfully remarked that the other two sisters had gone away to get married.

After passing through the fjord we landed at Hellesylt. From there we took stolecarrie for Grodaas on the Horningsdals Lake. At starting the road is as steep as the face of a mountain, which it is. The track has been very cleverly engineered in twines and turns to make it easier for the horses. It is so steep that we prefer to walk up the hill and let the stolecarrie follow after. The walk was very enjoyable, for at the turnings of this winding way we came upon a series of beautiful views of Hellesylt and the fjord beyond, continually changing as we ascended. On our upward way we came upon a party of Americans and carriages coming down, they, too, were walking, thinking it too steep to venture down in their conveyances. We thought it too steep to ride up, they thought it too steep to ride down; so you can understand it was pretty bad. As soon as we got over

this hill of difficulty we took our seats in the stolecarrie and stepped along at a brisk pace through plantations of trees and over a good but mountainous road, and as we neared Grodaas we descended into the valley in which it nestles rich in vegetation with green-clad hills and gurgling glens between. This valley was very English in appearance. It is a marvellous thing in this country how a few miles only separate the most barren lands, where scarce a sea-gull could exist, from such a spot as this, rich in verdure and vegetation. As we arrive at the hotel we again meet our American friends, who are just starting for Faleide.

We stayed here overnight. The hotel stands on the edge of the Horningsdals Lake in a very charming situation. It has a veranda running along all the length of the house which commands a view of the full extent of the lake, starting at our feet and receding miles away into the dim distance of mist.

There was a small quay belonging to the house which ran right into the water from the side of the hotel, and there was a very comfortable looking bathing box on it. We half made up our minds before going to bed that we would go down there and have a plunge in the morning. When we got up, I looked out and it was very tempting, for the sun was shining brightly. I asked Jack if he was coming, he said he didn't care about it. All undressed as I had got out of bed, I wrapped myself in a waterproof, put on a pair of slippers, and away I went to have my bath. The air was delightfully warm, and all went well until I put my feet on the steps under the water, which were all coated with a green, weedy stuff; on this I slipped, and away I went down to the bottom, about ten feet deep. And oh, the coldness of that dip!—ice seemed nothing to it. Up I came, and scrambled out as quickly as possible, with not a feeling about me but freezing cold. I never took into account that the temperature of the lake would be that of snow and ice water which was continually descending from the surrounding hills; but a good rubbing up with a rough towel soon set in a reaction, and all in a glow I walked back to my bedroom much the better for my bath in spite of Jack sitting grinning at my mishap, which he had seen from the window.

MARK OUTE.

FIFTEEN YEARS' EXPERIENCE OF A DAGUERREOTYPYER.

[A Communication to the Society of Amateur Photographers of New York.]

IN response to the request of your Corresponding Secretary, Mr. Duffield, I hereby give an outline of my experience in the history of the Daguerreotype, for a period of fifteen years. The details of this antiquated, senior branch of your art can interest you only in such parts as are similar. A comparison of the two, however, will show the progress of the half century we commemorate to-day, as also the centennial of the birth of Daguerre.

The first Daguerreotype I saw was made by Robert Cornelius, in Philadelphia. His laboratory was conspicuous. On the outside could be seen a large mirror, swung on a bracket, for illuminating his sitters with reflected sunlight. The use of bromine was not yet known in 1840, but Boudine introduced it soon after. In the same year Robert Chilton called on my brother to make hyposulphite of soda, offering four and a half dollars per pound, stating that the French article cost over five dollars to import, although still impure. Thus the first hypo was made here at the corner of Twenty-third-street and Fourth-avenue, the present site of the Young Men's Christian Association. Orders for other chemicals followed, and in 1843 Louis Becker was the first to manufacture photographic chemicals exclusively, at Old York-road, Philadelphia.

In the same year I entered the Daguerreotype business of Mr. Fred Langenheim, in the Merchants' Exchange of Philadelphia. Here there was little to be seen of the things you see nowadays in a photographic art gallery. A kind of a hiding-place for a dark room, and a spyglass-like camera, were all the indications of the mystery I was to learn. The camera rested on a candlestick-like tripod, with three set screws for adjustment, and was placed on an ordinary table. To interchange the ground glass and round Daguerreotype plate, it was necessary to unscrew a flanged ring and replace the same by a reverse motion. For the adjustment of the focus there was the rack and pinion, as Voigtlander's instruments still have. This instrument was one of the first made according to the mathematical calculations of Professor Petzval, of Vienna, having two achromatic lenses. It had been sent by young Voigtlander to his college-mate, William Langenheim, as a present, with supplies and instructions, but also the warning not to try Daguerreotyping unless he had courage enough to try five hundred times more after failing with the first hundred pictures. William Langenheim, a lawyer, did not have the courage, but his brother Fred had, and succeeded so well that he was offered six hundred dollars for that odd camera.

The manipulations of preparing a Daguerreotype plate will not interest you much. I should state, however, that the production of a chemically clean surface on silver is a difficulty that increases fourfold with the size of the plate. Another difficulty is the use of the chemicals in a volatile state. The iodine can be controlled by sight with faint daylight, but the bromine only by even temperature and constant practice.

At Langenheim's, necessity soon introduced a square camera with square plates and holders. A high tripod was also used instead of the table. In the

summer of 1843 the first dozen of small Voigtlander objectives, such as are still on the market, were imported. Soon after four larger ones, for 6×8 inch pictures, arrived. In the fall of that year Phillip Hass, formerly of Paris, showed Fizeau's method of fixing the image on the plate by cold gilding. Soon after the picture was made more brilliant by heating the plate while the gold solution was on it. In that winter the first polishing wheel was made. It was constructed like an ordinary grindstone, worked by a treadle, the wheel being cushioned and covered with buckskin. With the aid of this machine, and after weeks of hard labour and many experiments, we succeeded in making the first good large Daguerreotype of 6×8 inches, called whole-size; half and two-thirds-size were advertised and made with success. At that time we also succeeded in making a picture of a sick lady at her own residence, which was then considered impossible.

In the spring of 1844 Mr. Edward White bought one of the large Voigtlander instruments, and for him I made the first large Daguerreotypes in this city at 175, Broadway. There were then but a few Daguerreians here. They were—J. Gurney, Anthony, Edwards & Chilton, Augustus Morand, Van Loan, Burgess, Brush, Weston, Artho, Trisley, Plumb, and others I cannot recall. I remained with Edward White until December, 1844, when it became impossible to make a picture in his operating room on account of the extreme cold, for Mr. White would not allow a fire in the place overnight. Then I commenced business for myself, at the corner of Nassau-street and John-street, and after May, 1845, at 201, Broadway, under the firm of Langenheim & Beckers, agents for Voigtlander & Louis Beckers.

At that time the large Voigtlander objectives had a chemical and a visual focus, so that in order to make a large, near picture, the lenses were moved out one-eighth of an inch, while for usual work the ground glass was set permanently one-sixteenth of an inch nearer than the plate. That summer I took a view of High Bridge before the scaffolding was removed. This picture was taken for the engineers, and was, perhaps, the first one ever taken here in aid of architecture. By taking outdoor views I discovered that the plates increased in sensitiveness with the time between the preparation and exposure.

In 1847 I began to use a speculum metal mirror, in order to have my pictures not inverted. For very unsymmetrical faces this arrangement was quite indispensable in order to get a likeness. The mirror was attached to the instrument at an angle of forty-five degrees. The use of the mirror required double the time of exposure. It was made by Fitz, senior, the optician, and was used for years after.

In 1848 Fred Langenheim bought Fox Talbot's patent for the United States, at six thousand dollars. He introduced it here and failed in the undertaking.

In 1849 my firm was changed to Beckers & Fialil. Having now more time, we succeeded in substituting machinery for cleaning our plates, and thus obtained cleaner and better plates in one-third the time required by hand.

In 1852 M. M. Root, of Philadelphia, made two pictures on one plate; we succeeded in making four on one plate, and in such a way that the exposed quarter was in the centre of the field of the lens. It was then a great relief, as locket pictures were in fashion. In 1856 Mr. Ormsbee patented this same multiplying plate holder, and collected considerable money on it, until my priority made his claim void in the lawsuit brought as a test.

The production of stereoscopic portraits was the next task. Marchner, of Philadelphia, made patent cases to show these pictures in a very neat way. In 1854 F. Langenheim had commenced to manufacture stereoscopic views on glass. He sent me three dozen of his make to find sale for them here. At the first exhibit of these pictures one dozen of them were broken. This loss set me to thinking how to find an arrangement to show and secure the pictures against breakage, and in 1857 I obtained a patent for my revolving stereoscope. The increasing demand for this machine induced me to sell my Daguerreotype business in 1858.

Thus I was relieved from satisfying the vanity of each individual beauty of this world, and ended my career as a Daguerreian. ALEXANDER BECKERS.

PHOTOGRAPHY IN JAPAN.

Mr. W. K. BURTON writes to the *Japan Mail* of June 5 to the following effect:—

"I ask leave to tell your readers that the Photographic Society of Japan has now been duly constituted. There are already nearly sixty members, of whom very nearly one half are Japanese. There are a few professional photographers, but the great majority are amateurs. I am glad to be able to state that His Excellency Viscount Enomoto, Minister of Education for Japan, has consented to be nominated as President. The Vice-Presidents are Professor D. Kikuchi, M. A. Cantab, Director of the College of Science, Imperial University, and Dr. W. S. Bigelow; the Secretaries are Professors H. Ishikawa and W. K. Burton; and the Treasurer is Mr. T. Asanuma, of Honecho, Tokyo. These are all *ex-officio* members of the Committee, and besides them there are Professor C. D. West and Mr. Kajima Masanosuke. . . .

"All communications concerning the Society should be directed either to Mr. Ishikawa, at No. 5, Minami Nabecho, Ichome, Tokyo, or to myself at the address given below, W. K. Burton, College of Engineering, Imperial University, Tokio."

Foreign Notes and News.

THE combined Exhibition of the three Societies—the German and the Silesian Societies of Friends of Photography, and the Club for the Promotion of Photography—designed to celebrate the jubilee of the existence of photography as an art and science, has met with most unexpected support since the rooms of the Royal "Kreigsacademie" have been granted for the purposes of the Exhibition. The problem which the promoters have set themselves is to present as full and complete a view as possible of the many-sided development which photography has undergone during the last fifty years, and to show how wide an application it has found in art, science, and industry, and in all departments of civilised life. As far as can be at present judged, it appears that astronomy and spectro-photography, as well as the various methods of printing, will be most brilliantly represented. The Observatories of Potsdam, Pulkowa, Greenwich, Herény (Hungary), Paris, Boston, and Mount Hamilton, have announced their intention of taking part in the Exhibition, as also the Belgian Photographic Society. The Exhibition will open on August 19—the birthday of photography—the date on which Daguerre, fifty years ago, announced his discovery in a lecture delivered in the "Palais Mazarin" in Paris.

Mons. A. ROSSIGNOL writes to the *Amateur Photographic* as follows:—"Photographs obtained by means of a telescope of objects at a distance are comparable to photo-micrographic enlargements. The image formed at the focus of the object glass of the telescope is very small. But as the last glass of the eyepiece renders the rays of light almost parallel, nothing prevents the image from being repeated at the focus of the photographic objective, just as if non-distant objects had been taken, so that it is sufficient to direct the telescope towards the object which it is desired to photograph, and to focus it in the usual manner. An ordinary photographic apparatus is then placed in a line with the axis of the telescope and the eyepiece, and the focussing of the enlarged image completed by conveniently shifting the ground glass plate. This method, however, is open to the same objection as the production of photo-micrographs by means of an eyepiece, the last lens, acting as the objective in relation to the small image, is deficient in proper curvature and is not achromatic. This, at least, as much as any other cause, may be advanced as an explanation of the want of sharpness shown by the proofs thus obtained. Owing to the distance, moreover, the movements of the intervening air, especially when it becomes heated in the summer, render the formation of satisfactory images an impossibility, even where the most improved optical instruments are employed."

Our Editorial Table.

ELECTRIC LIGHT FOR THE MILLION.

By ARTHUR FREDERICK GUY.

THIS booklet (published by Simpkin, Marshall, & Co., price 6d.), imparts concise practical information on electric lighting and its cost to the uninitiated, and explains many things that have hitherto been mysteries.

THE WILD NORTH COAST.

A. JOHNSTON, Bridge-street, Wick.

THIS is a series of views photographed from drawings by Mr. Johnston, whose artistic *forte* we had until now imagined to have been confined to photography, in which we know him to be a proficient. In these sketches of the wild north Mr. Johnston has used his pencil with much effect, although for the sake of a rock-bound coast which we have seen under conditions of greater placidity, we could have wished that he had not invariably secured nature in such an angry mood, fulfilling Vedder's description of the—

"Land of the whirlpool, torrent, foam,
Where oceans meet in maddening shock;
The beetling cliff, the shelving holm,
The dark, insidious rock."

We have seen these scenes under other atmospheric conditions, when the ocean lay like a mirror, calm and quiescent, its contact with the iron-bound coast scarce creating a murmur.

These drawings depict some of the best-known rock scenes in the extreme north of Scotland and islands beyond, some of them bearing the descriptive title "Old Man," such as the *Old Man of Wick* and the *Old Man of Hoy*, the term in question being an evolution from the Scandinavian *Alt Mann* (high rock), descending by a stage easy to Scotchmen to "Auld Man"—"Old Man."

The views are all most effective, although we might notice Keiss Castle, Brig-o'-Trams, and the Brough as being especially so.

Is a sample of graduated cloth received from Messrs. Marion & Co. we find just the thing for which many photographers have long breathed aspirations. Commencing with a light drab, the colour goes on deepening by imperceptible gradations until it has become quite dark. In the hands of a clever photographer, or one who knows how to use a background, this graduated cloth places quite a power at his disposal. The material is woollen, and is quite pliant and flexible.

MR. JONATHAN FALLOWFIELD sends us a pint bottle of hydroquinone developer mixed ready for use in one solution. No directions for its use are necessary. In trying it we merely poured from the bottle enough to cover the plate, and the image came out evenly and well. The transparency thus developed is now mounted and forms an item in the editorial collection of slides worthy of being looked at.

" 8	Manchester Photo. Society	Masons Hall Tavern, Basinghall-st.
" 8	London and Provincial	

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JULY 25,—MR. J. TRAIL TAYLOR in the chair.

The CHAIRMAN showed some flash-light portraits, the work of Mr. T. H. McCollin. The arrangement for burning the magnesium consisted of a pan for holding "Blitz powder," a pyrotechnic compound containing a large proportion of magnesium powder, and an air jet which, on pressure of a rubber ball, blew through a flame on to the mixture and ignited it. The photographs were much admired for their satisfactory lighting and absence of any appearance of blinking, and the Chairman said that he would bring the lamp and powder to some future meeting for demonstration.

In answer to a question, the CHAIRMAN said that no reflector had been used; Mr. McCollin preferred to use a large quantity of powder and dispense with reflectors. The flame was very large, and that assisted in the evenness of the lighting.

Mr. A. Cowan then showed some plates, the result of some sensitizer experiments with various developers—pyro, ferrous oxalate, hydroquinone, and a new product called Eikonogen, and the latter showed the highest number. He also showed a transparency on chloride plate developed with the same substance in a less active condition, that is, after it had been used for many plates in succession. The tone was good and warm but the action still very rapid, development being complete in half a minute.

The CHAIRMAN had been trying Eikonogen developer the previous evening for negatives, transparencies, and for paper, and was perfectly charmed with it.

In reply to an inquiry as to the composition of Eikonogen, Mr. F. P. CEMBRANO said that analysis had shown it to be $C_{10}H_5$ in conjunction with SO_2 , Na , O , H , NH_3 .

Mr. A. HADDON then discoursed on the subject announced for the evening—*Sensitising and Resensitising Albumen Paper*. He had started by floating albumen paper on a filty-grain bath, and then, when nearly dry, floating it upon two successive dishes of distilled water, so as to remove almost the whole of the free nitrate of silver. A print on this paper was shown, and was exceedingly weak. The paper was then fumed for ten minutes in ammonia gas, and pads of eight thicknesses of blotting paper, also fumed, were used for backing up while printing. The result was now very much better. He had also tried to remove the whole of the free nitrate by soaking this washed paper in three changes of water and then adding salt, but the paper still printed, although with extreme faintness. Fuming again gave much better results. Another experiment was to float the washed paper, back downwards, on a solution of sodic citrate at ten per cent. Rochelle salt at ten per cent. was also tried. Both these substances appeared to improve the vigour of the print. Carbonate of soda was also tried in a similar way. Next, some of the washed paper was floated on a five per cent. solution of nitrite of potash; the result was far superior to any of the others when there was no fuming. Fuming, however, improved all.

The CHAIRMAN said that Americans invariably employed fuming and sensitising on a strong bath. Toning was much more easily effected on fumed paper. He had met with some ready-sensitized paper that would not tone as it was, but after a prolonged fuming toned readily.

Mr. W. E. DEBENHAM had, some two years since, met with a similar result. In this case, however, the paper was some which toned readily when fresh but if kept loose in a warm place for a day or two gave only a rusty-looking print. After fuming for a long time—twice or three times as long as for ordinary paper—it again became usable. He noted in all Mr. Haddon's prints a certain appearance as if there had been difficulty in toning—a peculiar, almost cork-colour effect on the light half tones.

Mr. HADDON said that that was so. He did not consider the paper equal to that sensitised and printed unwashed in the ordinary way. With paper containing the full quantity of nitrate of silver the free chlorine given off whilst printing converted more of the nitrate into chloride, and so a stronger image was obtained.

The CHAIRMAN, in thanking Mr. Haddon for his communication, referred to the benefit of having the results of such strictly comparative experiments as those Mr. Haddon had described.

With reference to the subject for the next meeting—Mr. Friese Greene's communication regarding photographing on so-called opal cards—the CHAIRMAN mentioned some very fine results obtained on Brinckerhoff's paper, which was understood to be prepared with gelatine and a white pigment, such as sulphate of barium or oxide of zinc.

BATH PHOTOGRAPHIC SOCIETY.

MR. AND MRS. PUMPHREY's garden party, given to the members of the above Society, took place on Tuesday, the 23rd ultimo, and, considering the unsettled state of the weather, was well attended. The President escorted the company over the various places of scientific interest and the tastefully arranged grounds. Occasional showers necessitated shelter being taken in some of the many retreats, in all of which our host and hostess had provided ample refreshment. A string band added to the general enjoyment.

Saturday, July 27, outdoor meeting at Chepstow, thence to Tintern Abbey *via* the Severn Tunnel.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

JULY 25,—MR. A. W. BEER in the chair.

Mr. Harry Holt was elected a member.

Mr. W. TOMKINSON reported upon the excursion to the Bollin Valley on Saturday, June 29. The party numbered sixteen (including two ladies). On arrival at Manchester, the party was met by Mr. Davenport, Vice-President of the Manchester Photographic Society, who proved a courteous and attentive guide. They then proceeded to Oxford-road station (Mid Cheshire Railway) and took train to Altrincham, eight miles; here they engaged three conveyances and had a pleasant drive of three miles (passing the celebrated church of Bowdon) to Rostherne Village, and the lovely Rostherne Mere, one of the largest Cheshire meres. Towards the south the banks gradually rise to a considerable height, and, being well wooded, form a most charming feature in the landscape. Overlooking the lake on the south is the pretty church of Rostherne, embowered in trees, and the *beau ideal* of a sequestered country church. The churchyard is entered by a picturesque old lych gate. The church dates from 1533. The former picturesqueness given to the body of the building by the row of dormer windows has been much interfered with by recent restoration (?)

Here operations with the cameras began in earnest, and were continued until five o'clock, when a comfortable tea was served in one of the cottages, after which the party proceeded by a charming walk across the Birken and Bollin Valleys to Ashley Mill, where the prize picture was obtained. Two groups were taken as a conclusion, and after a pleasant saunter (with two or three stray shots on the way through charming scenery) they arrived at Peel Causeway Station. There tickets were taken for Manchester in time for the home train at half-past nine, having enjoyed a very pleasant half holiday, the weather being all that could be desired. The work of the day resulting in one hundred and six exposures.

Respecting the excursion to Chester on July 13, Mr. TUNSTALL reported that owing to the unfavourable weather only a few members turned up, and operations were confined to the Cathedral. Facilities are granted to photographers at Chester which he hoped could be obtained at other cathedrals. The full muster was seven and twenty exposures made.

The PRESIDENT announced that the Judges—Messrs. Sayce, Atkins, and himself—had unanimously awarded the medal to Mr. William Tomkinson for the best picture taken at the Bollin Valley excursion. He was glad the Manchester Society had shown such a kindly spirit of fraternising, and felt sure good results would be attained by its adoption.

The HON. SECRETARY read circular note from Mr. J. J. Briginshaw calling attention to the Photographic Convention of the United Kingdom to be held from August 19 to 24 inclusive; also to the Exhibition of the Photographic Society of Great Britain to be held in the Gallery of the Royal Society of Painters in Water Colours, 5A, Pall Mall East, from September 30 to November 13; and to the Exhibition in the Town Hall, Cardiff, by the Amateur Photographic Society, from October 9 to 19.

Attention was drawn to Oldham's patent dry powder developer (quinol), a sample of which had been tried and proved satisfactory.

The PRESIDENT, referring to Dr. Backelandt's patent water developing dry plates, said he could not give a very favourable report. The Hon. Secretary had also tried a sample with similar results.

A vote of thanks was accorded the editors of *Photography* for allowing the competition prints of "Interiors" to remain in the room for inspection. These consist of some very choice specimens of photography upon this the most difficult branch of the art. The gentlemen who adjudicated must have had an onerous duty, as many were of such excellence as to run those awarded the first, second, and third places very closely. It is gratifying to record that the President, Mr. A. W. Beer, has obtained the second prize.

Mr. R. Crowe submitted his adapter for using smaller sized slides, by which the operator could use different sized slides in addition to those belonging to the camera in use.

Wolff's patent adhesive mounts were shown and distributed, also Talbot and Famer's exposure tables; and a selection of single lenses which had been sent by Messrs. Hockin, Wilson, & Co. for inspection.

Mr. J. A. Forrest exhibited pictures of Dolgelly and Barmouth taken by a lens by Ross (forty years old); these were highly creditable.

Pictures of Ceylon scenery by H. Holt, and competition prints taken at the Bollin Valley excursion, were on the screen for inspection in addition to the *Photography* competition prints.

NOTTINGHAMSHIRE AMATEUR PHOTOGRAPHIC ASSOCIATION.

A SPECIAL general meeting of this Association was held on July 22, Mr. Henry Blandy (President) in the chair. There was a good attendance, the Hon. Secretary having announced an exhibition of detective cameras; also to consider the proposal of the Committee as to the advisability of admitting lady amateurs to membership of this Association.

Correspondence having been read by the Secretary from several firms making detective cameras regretting their inability to send one for exhibition owing to pressure of orders, the HON. SECRETARY proceeded to explain and show the working of Dr. Kruener's book camera; also Messrs. R. & J. Beck's.

Mr. J. FURLEY LEWIS explained and showed the Kodak, passing round prints taken during a trip across to Bay of Biscay.

Mr. GEORGE SMITH exhibited and explained "The Optimus" and two others. The PRESIDENT, in opening the discussion upon the question of admitting ladies to membership, said he would read the last two circulars from the Secretary upon the subject, a copy of which every member would have received. He would then answer several objections that had been sent to the Secretary by some of the Members, which had received his careful attention, and he hoped to meet all in a satisfactory manner.

The discussion following was very animated. An amendment, proposed by Mr. S. Wells, seconded by Dr. Marriott, was put first and lost; upon the proposition being put, a ballot was demanded. The result being twelve for, eight against, many of the members refraining from voting.

IPSWICH PHOTOGRAPHIC SOCIETY.

THE monthly excursion on Saturday last, July 27, was, by permission of Lord Toller-mache, to Helmingham Park. There was a full muster of members, including their veteran President, Mr. J. Dixon Piper.

After a pleasant drive in a two-horse brake, Helmingham was reached shortly after three o'clock, and the party was met by Mr. Orchard, a resident member of the Society, who acted as guide.

Helmingham Hall is a fine old Elizabethan mansion, and is surrounded by a wide moat with a drawbridge, which is raised every night at ten o'clock. There is a fine library containing many rare books, including the first book printed by Caxton. There is also a lute left by Queen Elizabeth as a heirloom to the family. The church contains some very fine monuments to the Toller-mache family.

After a pleasant walk across the park to Mr. Orchard's residence, we found that Mrs. Orchard had generously provided a tea in the schoolroom, which came "as a boon and a blessing to men" who had been rambling in the fresh country air for three hours, so that it is needless to say how thoroughly it was enjoyed. Mr. Orchard is a successful beekeeper, and it was interesting to be shown his apiary. A start for home was made about half-past seven, and a pleasant afternoon's outing brought to a close about nine o'clock.

CARDIFF AMATEUR PHOTOGRAPHIC SOCIETY.

JULY 23.—Mr. S. W. Allen in the chair.

Messrs. Daniel Jones, F. Coleridge Boles, Charles Huxtable, and E. I. Champagne-Smith were elected members.

A Sub-Committee was formed to make certain alterations and additions to the studio, and Mr. Jostl kindly intimated his intention of giving at stated intervals instructions in lighting and posing.

The recent excursions to Margam Abbey and Walnut Tree resulted in some first-class specimens of landscape photography, &c., which were passed round for inspection.

Several details connected with the forthcoming Exhibition were dealt with.

The next excursion is arranged for Barry on August 3.

SOCIETY OF AMATEUR PHOTOGRAPHERS OF NEW YORK.

JULY 11.—President Canfield in the chair.

Mr. JAMES H. STERNBERG read a paper entitled, *Suggestions as to the Use of Certain New Organic Reducing Agents as Developers*.

Mr. F. C. BRACH exhibited a new camera with the following explanations. The camera which I have the pleasure of explaining to you this evening is a view camera, made by Messrs. S. Wing & Co., Boston. This size is adapted for 5x8 plates, and has a reversible back, so that the plate can be used up or horizontally. I notice one improvement is in the method of fastening the folding bell. In some cameras the method used is an ordinary thumb screw to lock the bell. In others there are two pivoted hooks, which, in being pushed down, clamp the bell. This construction is based somewhat on the plan, but in a slightly different way. A flat spring hook is attached to the under size of the centre brace of the bottom of the bell. The brace is pivoted to inside of the rear cross bar of bell, and when you turn the bell down the spring underneath still stays up above the central cross bar until you press down the central portion of the folding bell with your thumb. When you do that the bell is

clamped by the hook and held rigid, permitting the rear of the camera to be drawn out. Then I should call your attention to another point, and that is, that in the front portion of the camera, at the top, are inserted two levels—one for the up-and-down adjustment, and the other for the side adjustment of the camera. The intention is that the camera shall be placed exactly level, no matter if the object which you are going to photograph is on a high hill. Another peculiar feature is the compound rising front. Ordinarily a rising front is made on one board, which is raised and put in place and fastened with a thumb screw. In this case it is divided into three sections, so that one slides upon the other, and this allows the lens to be pushed down almost to the bottom or nearly to the top of the camera. Another feature of this adjustment is that the lens is held in both the first and second sections of the rising front, and it is because the rising front has to be so thick that it is divided into these different sections. Now I will proceed to level the camera, and then show you the adjustment of the lens, which is another novel feature. We will suppose that we are levelling the camera. [At this point some one objected that the camera stood so high, one could not see the levels.] Mr. Beach replied: I have always adopted the method, in taking a view, of having the camera legs spread out well, then you have a better base, which, as you will observe, lowers the camera enough. The point about the adjustment is, that the lens is inserted in a ball-and-socket joint, and now is pointing up as if one were taking a view of a house on a hill. If it is desired to change the adjustment, all you have to do is to rotate the flange ring in front here on the rising front, and in thus loosening the ball-and-socket joint the lens can be tilted horizontally, and then, by screwing up the flange, it is locked and held in position. The object of that is to do away with all the swing-backs in the camera, and you adjust the view by raising the front and tilting the lens either up or down. You see it works very easily. In regard to the back attachment, there is simply a frame, something like the Blair camera, and it has opposite the ground glass the arrangement similar to that which is used in an ordinary plate holder. The ground glass is forced forward by two springs, and on the extreme end, opposite to where the plate holder is inserted, is an ordinary flat spring which has a little pin attached to it which passes through here and operates on the plate holder. The plate holder itself is quite a novelty and quite a radical change; it is a metallic plate holder. It is scarcely any thicker than the ordinary plate, and is composed simply of a sack of tin which is nicely varnished, and the plate itself is carried on another sheet of tin stamped out the thickness of a plate. There is the plate holder and the plate [exhibiting them]. At one end of this septum is a spring. You simply push the plate in against that spring, and then let it slide back until the two little wire fingers on opposite ends of the holder overlap the plate and hold it. This septum, with the plate in, is then slid into the outer sheath. The operation of exposing a plate is quite simple. After you have inserted the plate in the septum, you simply push it home, and the push on the outer end of it makes a light-tight joint. There is also a little hole in the end of the septum here, into which the spring which I showed you on the back of camera catches. After pushing the plate holder into the back of the camera, when you draw the slide to make an exposure, you simply draw off the outer sheath, leave your plate exposed, and when you get through you put the sheath over again, and it is all done. Now I will show you how easy it is to put the plate in. There is a special light valve in the end of the ground-glass frame. This little spring on the outside end locks the septum, after the plate holder is pushed in. Now you cap the lens, and all you have to do is to draw off the sheath, and you can tell by the bright tin of the septum, seen through the ground glass, that you have drawn the slide sure. After you have made the exposure, you simply push it back, lift the flat spring with your finger and pull out your plate holder, and it is all exposed. When I first saw it I thought it was quite an idea and quite a radical change from what we have been accustomed to. The only point against it that I made was that the weight of the metal was too heavy; but I believe the makers claim that the weight of the tin or the metal is not more than the weight of an ordinary wooden plate holder, but I should rather try some experimental tests in weighing before I accepted it as being true.

Mr. A. PEEBLES SMITH then addressed the meeting on *The Making of Lantern Slides*. He said:—During the past winter I had occasion to make a number of slides for Professor Cromwell when he exhibited at the Grand Opera House. While doing that an old theory, to my mind, was exploded. That is, that the nearer the lantern is to the screen the denser the slide should be. His pictures, as you may well know, are enlarged up to about seventy-five feet square. The lantern is placed fully one hundred feet from the screen, and the slides which I first made went to pieces; they were too thin. I could not account for it, but went to work and made denser slides, with no better results. I soon found out that it was not density that was required, but the colour. The slide should be absolutely clear in the shadows and lights. Since then I have experimented with a great many developers, the effects of five having been shown here by the lantern, and I have decided in favour of antipyrine. I use it the same as I would hydroquinone; that is, take antipyrine, dissolve it in sulphate of soda solution, then make an alkali, the best alkali being caustic potash—the most active. Develop your plate. I have a brass plate about five inches in diameter. This is attached to a wheel under which is a lamp: the plate is heated and a centrifugal motion given to the plate, and while the plate is in motion the gelatine upon the plate is slightly softened, so that all the relief of development entirely disappears, leaving the gelatine free from veiling, which is often the case with gelatine slides. After that I used to varnish with collodion, which I have long since discontinued. I take an ordinary varnish, add to it one or two chemicals which are not commercial and in stock houses, but which can be obtained in drug stores the same as antipyrine, make a water varnish, and varnish the plate while wet, and then place away to dry, which gives a beautiful clear slide, as you can see by these which I pass around. They are free from grain and with apparently no density at all. But the lack of density is made up in the clearness of the lights and the clearness of the shadows. The reducing agent, antipyrine, is very slow, requiring at least thirty minutes to produce a slide. This, commercially, would be out of the way, as a man would starve to death making slides as a matter of necessity; but for the amateur who wants beautiful work on dry plates, he can do it. My next attempt after using this antipyrine was to try a etanediol. This is a

very insoluble chemical. I find it reduces much quicker on a slide plate than the antipyrine, but the deposit of silver is much coarser. That you can see from the slide exhibited. The formula that I have used with acetanilid is practically the same as the other. Of late I have been experimenting somewhat with collodion emulsions. Mr. Newcombe, of the Savill Company, has been at work all the winter in that direction. He has now an emulsion which more closely resembles the wet plate than any I have seen yet, in which a bath is used. With the collodion emulsion the great trouble seems to be that the film is too thick, and with it you get too strong a contrast. You take a very thin negative, one slightly under timed, and with collodion emulsion you get a negative beautifully clear in the lights and beautifully clear in the shadows, providing you do not develop the plate too quickly; and the great trouble with the wet plate process is that you are apt to have the developer too powerful, especially when pyro and alkalis are used. Iron is a little slower in its action, and you are not apt to get this strength in the slide. The objection to iron seems to be that it does not penetrate the collodion, and experiments made lately in that direction seem to be entirely in favour of pyro as a developer. I have a slide here which illustrates this emulsion of which I speak. As to hydroquinone being used as a developer for lantern slides, the formula which I use is one containing a great deal of sulphite, the alkalis used being phosphate of soda and caustics. After the slide has been developed I make a solution of carbonate of barium in water, which is poured over the slide, which acts as a cleaner. With hydroquinone as a developer for slides the colour which you get has a tendency more to warm tones, unless the negative be very dense, and for that reason I do not like it. I find that in slides, if you get a brownish black or a colour with a trace of pink in it, it is much prettier and will show to much better advantage on a large screen with the lantern a good distance from it than one containing the slightly reddish tone which hydroquinone gives. For that reason I use old developer with splendid results on dry plates, getting tones ranging from a warm tone to a blue-black. The blue-black can be obtained by making a solution of iron, say sixty degrees by the hydrometer, and adding to it from two to three drachms of sulphuric acid. Make a solution of oxalate of potash and add to that oxalic acid, both being put together in the usual way for oxalate developer, and then adding a little more sulphuric to the developer, you will get a tone ranging on the green-blue which you see in the exhibited slide, which gives it apparently no density, but on the screen it shows a pretty effect. If you have a tray of 5x8 inches, and you develop in it two slides, you can have the proportion of two ounces of oxalate to two drachms of iron solution. The sulphuric acid gives the cold greenish effect upon the Carbutt plate. I have used it on the Eastman plate, but you are not as sure of the tone on that plate, as that is a bromide of silver plate. For that reason the Carbutt plate gives the blue-black tone much easier. The method of developing these slides—quick development—seems to give the best results without graining. The usual method of producing slides has been by daylight, but I discarded that about six months ago, owing partially to my being so placed that I could not use daylight, and partially because I wished to experiment in another direction. I have since been using magnesium light altogether. There is a certain quality to the light used in making slides by magnesium that you do not get by daylight. For instance, you are exposing a plate to daylight; your lens is slightly stopped down and you make the exposure; the negative may not be even; you try to cut off the light here and there, and your light penetrates the shadows of the negative quicker than it does the lights, and the light detail is only obtained at the expense of the shadows. When you develop that plate your shadows come first, your lights lack the detail which we like to see in them, and the result is a sort of halation which runs through the plate and produces a sort of foggy. Your slide is not clear and does not show clear glass like the wet plate. The use of the magnesium ribbon prevents this, and you can set the light from any point. You can favour the sky or the shadows. One of the principal causes of halation is the light coming in around the edge of the plate and working its way into the plate as you develop. This can be prevented by making a mat, which you place in front of the slide before it is finished. This keeps all rays away from the plate with the exception of those which pass through the negative. The result is that the glass around the plate is perfectly clear and the light cannot work in where you do not want it. Now, as to the apparatus I employ in producing slides. It is so simple I think I will describe it. In the first place, I use an ordinary camera, as ordinary as anybody possesses. I have the kits (holders) ranged in a frame in a box 5x8, and in case some good-natured friend loans me a 11x14 negative, I can reduce that. If I am not using daylight I take a printing frame, which is the only handy thing I have in the house, 11x14; over that I place two or three sheets of cepa skin (thin tissue paper); behind that is a little box with the negatives in it; just beyond that is the camera with the lens. Now, in using the magnesium ribbon I use only two or three inches of it. When everything is in readiness to expose I have two or three little sheets of cepa skin; with the negative in its place, I hold that so as to simply allow the magnesium to come on those portions of the slide I desire. When the slide is developed you get that tone so much desired on dry plates, and you do not get that foggy in the lights you would get with daylight, because the exposure is rapid, that is, in comparison to daylight. It is this way: you expose by daylight; if you can do it and take your time you will get a very good slide, free from this foggy, but if you expose longer, for the reasons named, then the result is contrary. For focussing I place a lamp just back of the diffusing screen, and that illuminates the negative sufficient for focussing. Any lamp will do. The mat on the slides prevents that halation which I spoke of, and enables you to work without covering your camera or the box which holds the negative. There is light passing between the camera and the negative, but this mat so cuts off outside rays that you only get the light that passes through the camera.

Mr. BEACH: Do I understand that the screen is placed in front of the negative before your light?

Mr. SMITH: First is the magnesium, then the screen, and then the negative, camera, and plate. The magnesium is in front of the screen and diffusing the light. A number of people who have seen the apparatus which I employ seem astonished. They give me large negatives and wonder how I reduce them. But I do it by taking a printing frame of the size of the negative, placing the

negative in the printing frame and back of that the diffusing screen, the magnesium close to the diffusing screen, about six inches away from it, keeping the magnesium in motion while I am exposing the plate. The screen is only about an inch and a half from the negative. Then comes a little box arrangement which shades the negative from any rays that may come in over the top, and then comes the camera. Now as to dry plates compared with wet plates, there are points in favour of both. The wet plate gives you the clearest slide and the most freedom from grain. Clear lights and clear shadows can be obtained upon the dry plate with a good deal of care and skill and time expended. The wet plate possesses the advantage of being quicker, not in the sense of working, but the slides may be finished more quickly. The wet plate has this advantage, that with it the tones can be varied the same as on dry plates, but you do not preserve a certain tone value that you do in dry-plate slides. Myself, I prefer the wet plate. There are difficulties in the way of working it which everybody cannot overcome, and I think if the dry plate were worked up more it could be made to come up to the wet-plate standard as regards freedom from grain, which is essential. In dissolving acetanilid I use sulphuric acid and also alcohol, but you have to use them right in connexion with it. It precipitates itself; and by using a strong alkali I manage to produce the image, and afterwards, by a toning process, which I hope to explain later on in relation to dry-plate slides, I get the density required to make the thing a success.

Mr. STEBBINS: If I remember rightly, you stated that barium carbonate was a very good thing for clearing negatives from stains, &c. I cannot, for the life of me, understand why that should have any action whatever on the plate. Certainly it is a white powder, and I should think, instead of removing stains, it would have a tendency to produce white specks in the film. If Mr. Smith will explain how he overcomes this I will be obliged to him.

Mr. SMITH: Barium carbonate has been used in the wet process as a cleaner of collodion; that is, from the very fact of its being a precipitate, and precipitating on to the film it prevents anything that you are using in developing from working into the film itself. It has no cleaning action whatever on the plate.

Mr. BEACH: Do you rub the precipitate off?

Mr. SMITH: It is washed off. Instead of using alum, which has an action, I use that to cover the plate and do the chemical work while it is covered.

Mr. BEACH: I beg to differ a little from Mr. Smith's remarks as to shading the negative in reducing by daylight. I had a little experience last fall in making a number of slides. In two or three cases I had some negatives which were very clear in the shadows and very dense in the high lights, and the only manner in which I succeeded in reducing the slide equally was to take a piece of paper and hold it up in front of the shadow, allowing an exposure, say, of ten seconds originally for the whole negative, and then shading the shadows by moving in front of them this little piece of paper, and giving the high lights an exposure of perhaps a minute, so as to be sure to have an effect upon the dry plate; and the consequence was, when I developed the plate, the details all appeared in the high light just as nicely as they did in the shadow, and I got a very soft and beautiful slide; and I contend that can be done just as well by daylight as at night.

Mr. SMITH: One point further. In the use of magnesium on positives I do not shade with paper. I shade with colour screens, different colours acting differently on certain portions of the plate.

Mr. BEACH: I maintain that with daylight you can obtain just as nice and soft a tone on your slides as you can get by magnesium.

THE PHOTOGRAPHIC SOCIETY OF JAPAN.

A MEETING of the above Society was held on Friday, June 7, at the Chamber of Commerce, Tokyo. Professor Kikuchi took the chair at four p.m.

His Excellency Viscount Enomoto, Minister of Education, was elected to the post of President of the Society.

After some formal business the special business of the meeting was begun. This was a demonstration by Mr. K. Ogawa of Willis's platinotype process. The process of coating the paper was shown, and that of development was demonstrated on some prints that had previously been exposed to daylight in printing frames in the usual way.

There was a good attendance of those interested in the "black art," and they all took a keen interest in seeing the magic way in which the picture appears in the developing solution.

Mr. Ogawa spoke chiefly in Japanese, and some additional explanation was given by Professor W. K. Burton. It was explained that the paper was coated with a mixture of certain iron and platinum salts, that the light in the printing frame affected the former, which, in its turn, had the power, when dissolved by the developer, of reducing the platinum salt to the metallic state, so that an image in metallic platinum in a very fine state of division, or "platinum black," as it is commonly called, resulted.

Correspondence.

Correspondents should never write on both sides of the paper.

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

To the EDITOR.

SIR,—Kindly allow me through your columns to announce that the Photographic Convention will be opened on the 19th inst. at St. James's Hall, Piccadilly. The exhibits of apparatus and pictures will be of more than ordinary interest, and many promises of papers have come to hand.

From the numerous inquiries and correspondence that I receive, it does not appear that the objects of the Association are generally known outside the present membership. I take, therefore, the present opportunity to say that the Photographic Convention was established in 1886, on principles

similar to those of the British Association for the Advancement of Science. The increasing importance of photography, both as an art and a science, justified the formation of an Association devoted exclusively to its advancement.

The first meeting was held at Derby in 1886, and the increased numbers attending the yearly gatherings held subsequently at Glasgow and Birmingham—opened in each case by the Mayor of the town—make it clear that the objects of the Association need only be made known to be fully appreciated, not only by those specially interested in photography, but by scientific men generally. The great interest displayed at each meeting in the papers and discussions, together with the exhibitions of pictures and apparatus, have incontestably proved the usefulness of this organization. Regarded as a means to the development and cultivation of all matters pertaining to photography, the wide and varied experience which such a large and representative body of members can bring to bear cannot fail to lead to important and practical results in the solution of the various problems connected with the scientific and theoretical, as well as with the practical and artistic sides of photography.—I am, yours, &c.,
128, Southwark-street, London, S.E., J. J. BRIGNSHAW, Hon. Sec.
July 31, 1889.

PYROCATECHIN AND BRENZCATECHIN.

To the Editor.

SIR,—Amongst the "Foreign Notes" in your issue of the 26th instant, I observe the following paragraph:—"Dr. Eder has recently pointed out the fact—which is, perhaps, not universally known—that both pyrocatechine and brenzcatechine are compounds isomeric with hydroquinone of the formula $C_6H_4(OH)_2$."

It may prevent misunderstanding if I point out that "pyrocatechin" and "brenzcatechin" are synonymous, the prefixes "pyro" and "brenz" having exactly the same significance, i.e., that the substance is formed with the aid of heat. The correct formula is $C_6H_4(OH)_2$, and not $C_6H_5(OH)_2$. Probably the latter is a printer's error.

The systematic name used by English chemists for pyrocatechin is catechol.—I am, yours, &c., C. H. BOYHAMLEY.

The Yorkshire College, July 27.

STEREOSCOPIC PHOTOGRAPHY.

To the Editor.

SIR,—I think it is now time that Mr. Heywood or Mr. Chadwick, or both, should hark back to the starting-point of the extraordinary hunt they have been leading your readers about stereoscopic photography. Mr. Chadwick replied in your columns to an article by "F. M. S." in another paper; I replied to Mr. Chadwick in the proper place—viz., where the original article appeared. Mr. Heywood, addressing a society in Manchester, ridicules statements which he is good enough to attribute to me. I deny having made any such statements, or any statements bearing such construction as Mr. Heywood put upon them, and I challenge Mr. H. to produce the passages where he finds the statements he fathers on me. Further, he attempts to make out a case for the stereoscope as an instrument conducing to artistic effect, simply by holding up statements partly mine, partly paraphrases of mine, to ridicule; he does not even make an attempt to argue the matter, and on my pointing out this somewhat strange diplomacy he still declines the challenge, and in yours of 26th instant he says the subject is Mr. Chadwick's, not his. If the subject is not his—and from his attitude I fancy it certainly is not his—why did he put his foot into it by meddling with—I don't say criticising—a subject of which he confesses he knows nothing, and on which he has to lean on Mr. Chadwick for support? Mr. Chadwick is well up in the subject, as his writings prove, and if Mr. Chadwick likes to debate the matter with me in your columns I am quite willing to let him start afresh or fall back on his original article, and I will meet him fairly and openly. But no more mockery, the last resource of a weak cause; and, above all, let us have something that has at least a semblance of logic. In Mr. Heywood's speeches and correspondence we have phrases about "slippant misleading papers," "shallow notions," "shameful libel," and so on, but beyond the phrases and their offensiveness we have nothing. Mr. Heywood, trying to get out of my somewhat reasonable remonstrance against the phrase "shameful libel," applied to what I ventured to write in opposition to Mr. Chadwick's opinions, gives us a neat little piece of sophistry, which might pass if the word "shameful" had been kept at home. In what possible way can Mr. Heywood's age and my jetticoats affect stereoscopic photography? Besides, I wore a kilt, usually with little trousers below it! If Mr. Heywood wants to argue, I'm there; if he wants to ballyrag I give in.

Mr. Chadwick is quite another foeman, and if I said anything offensive, as from his tone I fear I must have done, I apologise on the spot. Why he is at such pains to tell us when and where he saw Mr. Heywood of course I do not know. I never said he put up Mr. H. to the misplaced attack on me, and I never thought it.

About my phrase, "any other than a scientific interest," that is really an accurate quotation. I was wondering why he answered "F. M. S." in your columns and not in the other paper, when a person pointed out that Mr. C. was advertising in your and not in the other paper. Does Mr. Chadwick suppose that I was throwing a stone at him for making

cameras when I myself am open to photograph bacteria from any part of Mr. Chadwick's person, from his manservant, from his ox, or his ass, and to make and photograph sections from his dearest friend for a pecuniary consideration? Not much. Mr. Chadwick this time has been too fast to take offence, and he replies by a very funny retort about "Andrew Pringle, Esq." I suppose he thinks I am in the habit of signing myself "Esquire"—I did not think Mr. Chadwick was small—or perhaps it is another cut at the Convention.

Mr. Chadwick "does not remember" that the Manchester Society "made any great fuss of" me. My words were: "It is a Society, if I mistake not, to which I am personally indebted for kindness which I shall not in a hurry forget." Where's the fuss? How can anybody discuss matters in the face of this sort of thing?

In future I will reply only to matter touching the stereoscope, so far as these gentlemen are concerned.—I am, yours, &c., ANDREW PRINGLE.

THE FRENCH EXHIBITION.

To the Editor.

SIR,—I have received with great pleasure, as usual, THE BRITISH JOURNAL OF PHOTOGRAPHY of July 26th. While to some gallophobes Mr. Stebbing's answer (?) to E. Lisk's letter may prove satisfactory, I am sure that to the majority of the readers it will not prove anything, except, perhaps, that Mr. S. is short of arguments and proofs. This will especially be the case with Mr. F. York and others who have been there themselves, and able to know better.

Mr. S. is willing to admit the correctness of Mr. F. York's letter in regard to the Paris Exhibition—so do I, since Mr. York states the correct price of admission, and says that policemen do not bother you one after another, but ask you *politely* to move on when working out of regular hours, and he does not say that such a case entails loss of instruments or fine, but only the taking away of permit, which, after all, was of no more use. I would also state that Mr. F. York does not insinuate that parties getting into trouble (all of their own fault) are only foreigners, nor does he suggest that while gentlemen may get into trouble ladies should go free when they sin. Mr. F. York and I perfectly agree so far, as both our letters show (p. 483).

In Mr. S.'s answer I will call the attention of your readers to another mistake, viz., the permit does not limit the quantity of negatives that can be taken to a dozen, but you are at liberty to take as many as you can in the specified time *without* any extra pay whatever. One hundred with a Kodak if you choose, or with Eastman roller films, 22 inches wide, fifty if you like it.

Now, Mr. Stebbing is at liberty to print one more mistake, by stating the exact way the direction controls how many negatives a certain party has taken during the four hours of his permit. One, twelve, or twenty-four—or none. As to my ignorance of photography it is quite a personal matter of no public interest, and of which Mr. S. knows as little as he knows my name. If you know of a friend that wants to take views at the Paris Exhibition I will go with him once, and all I will ask from him will be a truthful letter of all that happens to us, and, when written, send it to you for publication.—I am, yours, &c., E. LISK.

Amherst, July 27, 1889.

DARK FLASHES.

To the Editor.

SIR,—I notice in your last JOURNAL a few words concerning "dark flashes," and from what I saw a short time since the explanation given by Professors S. and C. appears to be correct. In the afternoon of June 7th or 8th I was looking out of my window at some almost constant flashes, when there was a short pause followed by one very peculiar flash, apparently about 350 to 400 yards distant, and at a comparatively low angle. I will try to explain what seemed to occur. There was a sudden burst of light rather above any of the tallest trees that formed the background, and the flash continued to the earth leaving rather more than the upper third as a wide black streak, terminating suddenly in a very thin wavy line to the ground. The centre of the dark portion looked darker than the sides, and the duration of the flash was quite long enough to note what I have mentioned. The thunder was almost immediate, as one very loud, sharp burst. I think this is the only time in my life, either in this or the other hemisphere, that I have observed such a flash at sea or on land. The dark portion appeared to originate in its descent, and not absolutely at the exploding point. I regretted I had no person with me to compare notes, for we all know how easily we are deceived in our observations regarding lightning. I trust you are well and may enjoy yourself at the forthcoming Convention.—I am, yours, &c.,

Greenbank Park-road, Portwood, Southampton,
July 29, 1889.

R. L. MADDOX

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting of this Club, August 7, 1889, will be on *Purifying Water for Photographic Purposes*. Bank Holiday outing at Godalming. Trains from Waterloo at a quarter to ten.

Exchange Column.

*. * No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Wanted, good quarter-plate landscape lens; exchange magic lantern, nearly new, shows eight-feet disc.—Address, A. KEANON, 18, Roden-street, N.

Ross' 15x12 L. A. doublet to exchange for instantaneous doublet or similar lens by first-class maker. Difference adjusted.—Address, GILSON BROTHERS, Seacombe, Cheshire.

Wanted to exchange, accessory balustrade and steps in good condition for good unmounted specimens. Will send photograph in exchange for specimen print.—Address, JOHNSON, 44, Gilroy-road, Liverpool.

Will exchange Optimus rapid 7x5 Euryscope for larger lens same make, or Ross' rapid symmetrical, same size or larger. Difference adjusted.—Address, E. A. BASCHÉ, 6, Hartest-terrace, Mill-road, Cambridge.

Answers to Correspondents.

*. * Communications relating to Advertisements and general business affairs must be addressed to "H. GREENWOOD & Co.," 2, York-street, Covent Garden, London, W.C.

All matters for the text portion of this JOURNAL, including queries for "Answers" and "Exchanges," must be addressed to "THE EDITOR," 2, York-street, Covent Garden, London, W.C. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.

W. S.—If the negative sent is the best the lens will produce it must be of very inferior quality.

W. ANDREWS.—You may place absolute reliance on the quality of the lenses made by the firm mentioned.

DR. C. B.—Sorry we are unable to give the address of Rose & Dobson, the makers of the toughened glass.

D. CUNNINGHAM.—The cyanide of potassium employed by you has not been of a good quality, else must it have redissolved the precipitated cyanide of silver.

J. COX.—If, as you say, the developer "works all right," what does the slight discolouration matter! After the long keeping it is not a matter for surprise that it is slightly tinted.

A. Y. E.—Hunt's *Researches on Light* is now a very scarce work. Copies are to be met with occasionally on the second-hand bookstalls. There is little chance of it ever being reprinted.

JACK.—The *American Journal of Photography* (McCollin, Philadelphia), *The Photographic Times* (New York), and *Anthony's Photographic Bulletin* (New York). These will suffice for your purpose.

O. B.—Apply to the nearest chemist for litmus, make an aqueous infusion and steep the paper in it. If your litmus books have faded from exposure to an acid atmosphere, rinse in dilute ammonia and dry.

J. JOHNSTON.—Until we know what the invention is or in what it consists we cannot aid you. We cannot even guess at it from the specimens enclosed. Send particulars, and, if possible, we will assist you.

W. J.—If the spots can be seen on the paper before it is printed, there is no way of avoiding them in the finished picture. You will be perfectly justified in returning it to the dealer from whom it was obtained.

A. H. B.—The bromide enlargement has been very much under exposed. The longer the exposure the less will the "soot and whitewash" character prevail. Expose much longer, until the details in the faces are well brought out.

MACBETH.—Silver prints can be made by exposure to the electric light. But the light must be powerful and the exposure somewhat prolonged. This source of illumination would be much too costly for commercial silver printing.

A. J. B. inquired in our issue of July 12 where he could commence business in any town not inundated with club printers. In reply to this, "L. T." suggests his writing to V. P. Davis, Esq., 20, London-road South, Lowestoft, for information.

RUTLAND.—The lighting on the portrait marked "C" is decidedly the best and most effective. All the others are lighted too much from the front, hence their flat appearance. Follow on the lines upon which "C" was obtained; even in this a more decided side light would have been preferable.

B. A.—Your plan of testing, if all the silver is thrown down, is as good as any. From the result it is clear you have not added sufficient sulphide of potassium. The meaning of the term about which you inquire is that additional turbidity is manifest, if silver still be in solution, when more of the precipitant is added. Possibly your liver of sulphur has been exposed to the air, and has thereby become deteriorated.

S. TAYLOR.—If the mounts will not stand the test you have applied they are certainly unfit for their purpose. Of that there is no doubt.

S. B. R. complains that in mounting pictures with starch he cannot avoid lumps which cause unevenness, unless the starch is so thin that the pictures will not adhere. In applying the starch paste the lumps should be thoroughly broken up by the brush—this is not a difficult matter. Some apply the paste with a sponge; with this a uniform coating is easily obtained. Sometimes the starch is beaten up to a uniform mass in a basin with a spoon, or forced through a sieve before it is used.

A. BARTLETT.—Negative fixing baths are certainly worth saving for the silver they contain. If you send your residues to the refiner in small quantities only at a time you must not expect so large a return, proportionately, as if you sent bigger batches. The cost of reducing a small lot is, in proportion much more than a large one. We do not think the charge at all excessive. You must bear in mind the charge is based upon the time and material consumed, and not upon the amount of metal recovered.

C. W.—Evidently your previous communication, and the specimens, did not reach us. The cause of the foggy look of the prints appears to be due to contamination in the manipulations. The use of unclean dishes, for example, would fully account for it. If you wash prints, after fixing, in rusty iron pans there is little wonder that they turn out unsatisfactory. You had better have separate dishes for the different solutions, and keep them for their special purpose. The hot water has nothing to do with the trouble.

QUARTER-PLATES IN SWITZERLAND.—"Bex" kindly replies to the query of "L. M." in our issue of July 12 as follows:—"Quarter-plates (Hford) and all English sizes can be procured at Geneva, also plates by Lumière, Bernaert, Monckhoven, Engel, Tailfer, &c., but I do not know if in English sizes. Eastman's products can be got in almost every town. There are societies in Geneva, Zurich, and Lausanne. The latter has many English members who would willingly give information. If 'L. M.' is passing here I shall be glad to assist him." "Bex's" name and address may be ascertained on application to the Editor.

A. C. CALVERT writes: "I have always had much trouble in taking instantaneous photographs with an ordinary camera, and I shall be much indebted to you if you can help me out of my difficulties by recommending me some apparatus by which I could focus and see what I was taking at the same time as I set off the shutter. I do not want a detective camera. Do you know any of this kind in the market?"—View-meters, or finders, to fix on the camera are sold at every photographic warehouse. One of these will, doubtless, answer our correspondent's purpose. Mr. McKellen, of Manchester, we believe supplies a telescopic arrangement fitted to the camera, by which the image can be adjusted in focus and the view seen at the same time while the plate in the camera is ready for exposure.

LANTERNIST says: "Referring to the notice in your current issue upon *Copying Woodcuts for the Lantern*, which rather implies the practice of copying from 'the different illustrated periodicals,' I ask if such practice is legal without first obtaining, in each case, the permission of the publishers. I shall be only too delighted to learn that one is free to copy whatever may be so desired, my sole object being to make one (only) slide of each subject that is met with of sufficient interest for private lantern exhibition. I was greatly disappointed some months back upon writing to the publishers of *Punch* for permission to copy one particular illustration to be flatly refused, notwithstanding my assurance that the slide was to be used for private use only, or, at most, to be shown to a lot of school children for purely educational purposes."—The article does not imply that copies can be made without permission, for they certainly may not. It only referred to the practical part of copying woodcuts generally.

A. S. writes: "A few months ago I invited the mayor of this town to sit for a photograph, which he did; I submitted proofs, and after a time he came and paid for them, but did not order more. This week a history of the town and neighbourhood has been published, and in it is a portrait of the mayor from one of my photographs. My permission was not asked, which I should not trouble about if the name of the photographer was mentioned. I consider myself treated badly. Have I any recompense? The photographs not being copyrighted I am afraid I have not, but if I had the photographs registered now could I stop further liberties being taken with them by the same party—as, for instance, stopping his issuing any more books containing the said portrait? I shall feel obliged if you will tell me. I may mention that the mayor gave the publisher the photograph of himself."—Our correspondent has no remedy for his grievance, inasmuch as he has no copyright in the picture, he having been paid for taking the portrait. In this case the copyright is vested in the sitter, therefore if the picture were now registered it could not be made a valid copyright, except to the sitter. Had the portrait been taken without payment, and the sitter presented with a few copies for sitting, the case would have been different.—*Sulphate of iron*, not the sulphite. The precipitation should subside in a couple of days.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1527. Vol. XXXVI.—AUGUST 9, 1889.

EXPOSURE BY RULE.

Is it possible to exercise too great exactitude in aught that belongs to the practice of photography?

Conversing the other day with a friend, whose experience in the art is as ripe as his reputation is great, he provoked a smile by his graphic description of the behaviour of a party of—well, not very experienced—amateurs, who one day took a run out to a rather picturesque village situated a few miles south of the great metropolis.

Waiting their time till a pretty play of light and shade fell upon some object on which all were bent upon securing, fortune at the right moment favoured them still further by bringing, simultaneous with the fitful lighting, the living material for the most effective of foregrounds. Out came the note books with exposure tables, and busy, busy were the pencils engaged in working arithmetical problems to determine what should be the correct exposure to give for such and such a diaphragm.

But foregrounds of this class, like time and tide, wait for no man—not even for a body of gentlemen amateurs from London—and by the time the *f*-20's and *f*-30's of the diaphragms had been wedded to, or converted into their equivalents in seconds of time, the opportunity was lost.

We have seen the same thing. We have nothing to say against exposing plates by rule, aided by all the paraphernalia of note books, exposure tables, and actinometers—at proper time and place; but rules and laws, whether made for slaves or not, are out both of time and place, under circumstances such as those here indicated.

We once spent an evening seeing a professional architectural photographer develop plates of larger dimensions than those affected by the average amateur, and these represented much money, as they had cost him between three and four thousand miles of railway travelling. Each exposure had been made according to his judgment exercised at the moment; an entry was made in a note book, as a guide to the recognition of each subject after the proofs should have been printed, and this was all. In developing, the plates were treated in rotation, and such had been the soundness of judgment in exposing (although this ranged from a portion of a second up to half an hour) that not only was every negative good, but scarcely a single deviation had to be made from the ordinary routine of development. This friend would have laughed to scorn any one that even so much as named to him the employment of exposure tables or actinometers in connexion with his practice, yet his work is before the world as among the best in his special walk. We mention this by way of recommending the exercise of judgment to young amateurs, so as to be able to dispense with the interminable employment of tables and protracted arith-

metical calculations at a time when they should be otherwise engaged.

Notwithstanding what we have said, it must not be imagined that we counsel inexactness in aught vital to successful photographic practice. There are phases in the art in which it is impossible to be too exact—a fact well realised by the makers of emulsion dry plates or of lenses, in both of which success depends upon attention to the minutest things. But in gauging the intensity of light for exposures, or in developing a latent image, there is a certain degree of elasticity which permits of a departure from the ideal standard of perfection.

ECONOMY IN THE PRINTING ROOM.

RESIDUES—PRINT WASHINGS.

FROM a very early period in the practice of silver printing the saving of the precious metal contained in the washings of prints has been recommended, and in a more or less judicious manner carried out, hence there will be many to whom the following remarks may contain no considerable element of novelty, but at the same time, judging from the way in which the "saving" has been carried out in places we have visited, there is a still larger number whose practice is capable of considerable improvement. Let us follow the processes *seriatim*. The prints are washed, and the washing waters preserved. Many printers follow the practice of washing the prints in successive changes of water until the last water is scarcely milky. Now, as a matter of practice, unless the time allowed for the precipitated chloride to subside be very protracted, the whole amount in suspension does not entirely fall, and when the liquid is run off from the deposit, a certain percentage of waste occurs in consequence. This waste is naturally increased the greater the quantity of liquid in proportion to the silver present. It follows, then, that to collect the after washing waters, which, in comparison with the first, are only faintly milky, is quite false economy; the smaller the amount of water the better—consistent with the due carrying out of the main object of the process—the proper toning and fixing of the prints. The object to be borne in mind in these washing operations is the collecting the nitrate of silver solution—for such indeed it is—in as concentrated a form as possible. The value of this precaution is seen when the precipitation of the silver as chloride is brought about, for the stronger the solution the more readily the chloride clots, and the clearer will the supernatant fluid be. It is here where waste will always occur unless extensive precautions are taken, for it will be found that whenever the precipitant is in excess, as, of course, will usually

be the case, so as to ensure the avoidance of loss, there will always be a milkiness, which will persist for many days before entire deposition occurs. That the minimum of loss should be so produced, there should always be two vats in use—one for sediment to settle in, while the other was being gradually filled up, and so on. Also the spigot or other mode of exit for the waste solutions should be placed a considerable distance above the bottom of the precipitating vat, about one-third way up; some recommend it to be half way up the side. By this means the deposit is not stirred up and drawn out in the current, and the finer particles of sediment that have not quite settled to the bottom are also left behind.

We now come to the actual precipitation, this was almost invariably brought about (as chloride) by the addition of either common salt or hydrochloric acid, popularly termed "spirit of salt." The latter is decidedly to be recommended; it aids the clotting and falling of the precipitate, while salt tends to assist the persistence of the milkiness, and, in addition, possesses the grave disqualification of being able to dissolve a very appreciable portion of the chloride itself, and as we are directing our attention to economy, this is an important matter. The deposition also will be greatly facilitated by violent agitation for a short time. The liquid should be well shaken each time fresh print-washing water is added, and it will be as well to place in the collecting vessel, as soon as emptied, the amount of acid judged requisite for the vesselful. We need scarcely say that before running the liquid off after precipitation it should be tested by the addition of a drop of acid, to ascertain that no silver is left. It is the endeavour to save time and avoid this testing by always adding a large excess of salt that the solvent action of chloride of sodium, when it is made use of, is so wasteful of silver.

We may here record some experience we have been brought into contact with that will show where care must be exercised. In one case the utmost amount of silver extracted from the washings of some reams of paper was too insignificant to be worth taking trouble about. An investigation into the attendant circumstances revealed the fact that home-made "ready-sensitised paper had been employed, and its preparation was such as to leave little or no free silver in the paper. The albumenised paper was floated in the ordinary way, then well blotted off and finished by floating on a bath of citric acid. Here was no silver to dissolve into the washing water, and the precious metal lay in the blotting sheets, which in all probability had been thrown away."

In the next instance, in the endeavour to economise, not only had the preliminary washing been saved, but those washings also after taking the prints from the fixing. All, however, it turned out were collected in one vessel, and chloride of sodium naturally failed to produce any change. Some little time was spent in discovering these facts; but once known the explanation is so simple as to be scarcely necessary. There was sufficient hypo present for the silver to be converted into thio-sulphate, and from this of course chloride of sodium would throw down nothing. If hydrochloric acid had been used, a deposit would have taken place, but this would in the main have been sulphur, and the whole of the hypo present would have had to be decomposed before all the silver was extracted from the solution. This again would be false economy in every way.

In conclusion, we may say that where, from want of space and convenience, it is desired to include the process of collecting the silver, both from the print washings and the used "hypo" solutions in one operation, it may readily be done; but in that

case the suitable precipitant is sulphide of soda, employed as described in our first article of this series. Chloride of sodium is useless, hydrochloric acid would be required in large quantity, the precipitate would be largely contaminated with sulphur, and a penetrating smell of sulphurous acid would pervade the place. In this case liver of sulphur would be the most suitable, the simplest, and the most economical precipitant to employ.

COLOUR blindness is again occupying the attention of the Government, this time in connexion with the Mercantile Marine. One day last week the President of the Board of Trade, in reply to a question, said that the subject of colour blindness amongst seamen of the Mercantile Marine had been referred to a Departmental Committee to inquire into and report upon. Also that the Committee would have scientific assistance in the investigations. This is not the first time that this subject has been investigated officially, and the published reports show that this particular defect of vision prevails to a much larger extent than many appear to imagine. It must be very manifest that any one who cannot clearly distinguish between different colours—such as red and green, for example—is quite unfit for office, either on sea or land, where, perhaps, life and property are dependent upon colour signals.

It does not follow that because a person may possess a defective vision with respect to one colour that he will with all, for such is not the case. We have in our mind just now a photographer who is an artist in every sense of the word. His photographs are always highly commended for their artistic qualities wherever they are exhibited. But when he colours a portrait himself, as he sometimes does, although the work is always skilfully executed, it is eminently unsatisfactory. Blues predominate everywhere. The shadows, which should be cool grey, for instance, are represented by blue. Tints which ought to be, say, pale blue, or greyish blue, are either strongly pronounced or violent blues. In fact, in the pictures blue pervades everything. But if this were simply subdued the work would be really excellent, and the colouring perfectly harmonious.

SEVERAL photographers, we know, are to an extent colour blind without their being actually aware of the circumstance. Some printers, for example, cannot possibly tone a batch of prints all to the same shade, however careful they may be. And what is more, when the discrepancy is pointed out they fail to see any difference. Such, however, is the fact.

ACCORDING to a provincial paper an amateur photographer has recently had a narrow escape from poisoning by bichloride of mercury. He took about one hundred grains of the salt in mistake for hyposulphite of soda, so says the report. Bichloride of mercury is a deadly poison, three or four grains being considered a fatal dose. However, a simple and effective antidote for this poison is usually at hand, and it should be more generally known. If after it is taken one or two raw eggs be swallowed no serious result will follow. The salt combines with the egg and forms an insoluble compound which is inert. It goes without saying in all cases of poisoning that the antidote to be effective must be administered at once, before the poison is absorbed by the system. An egg or two is usually to be found in every house, or, if not, they can be quickly procured. Now that bichloride of mercury—"corrosive sublimate"—is so much used in photography, it cannot be too widely known that, in case of accident so simple a remedy, if applied without delay, may be the means of saving life.

In the report of the case alluded to above it is stated that the mercurial salt was taken in mistake for hyposulphite of soda. It would have been interesting to know why hyposulphite of soda should have been taken at all. A solution of the latter is not an agreeable beverage therefore we surmise it was to have been taken medicinally. Hypo

sulphite of soda may be good as medicine, but we have not heard of it being used in this direction, and it does not figure in the *Pharmacopœia*. Neither for that matter do many other substances which are employed as remedial agents. Perhaps, however, the case is not correctly reported.

SOME photographers are exceedingly careless with their chemicals and leave them about the house, notwithstanding that they may be of a dangerous character. An amusing instance of this occurred at the house of an amateur a short time back. He had left a parcel of hyposulphite of soda open in the scullery, and the servant, mistaking it for washing soda, added it freely to the water in which she boiled some vegetables to make them look green. The result was not altogether satisfactory.

EACH succeeding Bank Holiday appears to bring forth more photographic apparatus than any of its predecessors. This must have been eminently noticeable to every one who had business at the different railway termini on Monday last, or on the two or three days preceding it, notwithstanding the unpromising state of the weather. Camera stands and unmistakable photographic packages were to be seen almost everywhere.

AN universal kind of freemasonry at one time existed amongst amateur photographers. So there does now we are aware, but not to the same extent as of old. It is to be regretted that "snobbishness" is occasionally met with, and this was never the case a few years back. Then it was always with amateurs "hail fellow well met," though they might be perfect strangers to one another.

AN amusing incident is related which occurred on Monday last. An old portrait photographer, who when he takes a holiday always takes a light landscape camera with him, was photographing a few miles from town, when he was interviewed, very patronisingly, by a gentleman of the "masher" type, something after this fashion. "Ah! that is rather a good-looking camera you've got there, but you ought to put it more that way," &c. "Whose plates do you use?" On being told, he said, "Oh, they are no good, you should use So-and-so's, they are the best, I always use them myself, and my pictures are very beautiful; my friends say I should send them to the exhibitions." Next he said, looking at the photographer's stained fingers, "I presume you develop your own negatives; I always let — do mine. The man does not charge much, and he does my prints." Our friend replied that he preferred to develop his own. "Oh, I could do it, you know. I have seen it done, but it is so messy I could not tolerate it. How could one appear in company with dirty hands, you know?" After dogmatising on the arrangement of the picture, the interviewer remarked, "I've been photographing nearly three years, so you see I know something about it; how long have you practised it?" Our friend, who is fond of a joke, replied, quietly, "about twenty years professionally, and for many years prior as an amateur." This brought forth a cool "good day," and our friend has not yet decided whether the quick departure was due to the interviewer thinking it *infra dig* to talk with a professional, or to the humiliation he must have felt at having assumed the dictatorial tone he had to a veteran in the art.

THE question has frequently been raised in our columns as to what constitutes an amateur, and what a professional photographer. An equally interesting question would be, What constitutes a *photographer*? In the case cited above the plates are purchased and exposed. They are then sent to a professional photographer to develop and print from; he also mounts the prints. Yet the one who simply exposes them dubs himself a "photographer," and considers that he is justified in exhibiting the finished pictures in his own name. With the exception of the exposure of the plate, the whole of the work is that of a professional photographer. Does the mere exposure of the plate constitute a photographer?

ACCORDING to *Science*, experiments have recently been made that will be of interest to photographers, on account of their bearing

upon dark-room work and its effect on the eyesight. It should need no warning from us to point out the danger of carelessness with regard to the use of the eyes, yet there are many who fail to take the most elementary precautions. Thus, when at work the actual rays of coloured light from a window or lamp should never be allowed to fall on the eyes, and when passing out of the dark room into the brilliant light of the studio they should be exposed for the first moment or two to as little glare as possible. The experiments in question give the order in which a fatigued eye recovers the power of perceiving different colours. If the eye has been fatigued by long exposure to red, the sensitiveness to green is first restored, then blue, yellow, and, finally, red. After a blue fatigue, the order is yellow, red, green, blue; after a green fatigue, red, blue, yellow, green after yellow, it is red, blue, green, yellow.

THESE results, of course, refer to a fatigue of a stronger character than would usually be seen in prolonged dark-room work. There is, we take it, upon the theory of colour perception, so well expounded by Tyndall, an exaltation of sensitiveness to the rays not employed; the nerve endings not excited become more receptive, so that upon entry to the light studio the reception of the light is so strong as to become an actual shock, and to that extent must be injurious.

ON THE DETERIORATION OF DRY PLATES.

II.

IN my last article I referred to a few tests which I had made with plates kept for a lengthened period with the view of forming an opinion as to the keeping qualities of a gelatine dry plate. Within the last few days I have made further investigation into this interesting subject. In my recent tests I used plates dating back from 1882-1883, and these I have tested in as careful a manner as possible, exposing same both by contact and also through the camera, and using different developing formulae. These plates, until the hour of my using them, were never taken out of their wooden boxes, their wrappers were undisturbed; in fact, the boxes were just as they left the works—"Nelson's." As to their storing in the interval, they have been kept in a dry place and have not been subjected to any sudden change of temperature. I must say I looked forward with a certain amount of interest as to their behaviour. The first of these plates I exposed through the camera, and at the same time I ran alongside with it a fresh plate by one of the best makers of the day, and with which I was familiar. Both of these plates were subjected to exactly the same treatment, the same exposure, and were developed in the same tray with the same solution. The fresh plate turned out in every way a satisfactory negative; not so, I am sorry to say, did the old one, which turned out a miserable, flat, good-for-nothing result. A further series of exhaustive trials gave no better results. I then tried an ammonia plate I knew to be dated from 1886; it was a specially fast and good series at one time, but, horror of horrors, what a result now! It was at once apparent that dry plates in some cases much resemble eggs—age don't improve them.

Now, I am often asked by my pupils to account for this or that failure in their plates after exposure. A by no means uncommon experience on the part of an amateur when developing, no matter how carefully he may have studied his exposures and lighting, is to find on development, no matter how he strives to avoid it, that he cannot get anything but dull, flat results. At first it is very likely he thinks from the manner in which the plate behaves during development that he has overexposed it, and so the next is treated in a somewhat different manner. But all to no purpose. Then the lamp is judged as dangerous, or something has gone wrong with his chemicals, and very likely the last thing he thinks of is the plates, and this because he has used some of the same batch on a previous occasion with excellent results.

Just recently I had a very glaring case of this kind brought under my notice. One of the most careful and painstaking workers in the West of Scotland sent me several dozen plates to develop for him. Accompanying the plates were full details of *light, stop used, nature of subject*: in fact, everything needful for any one to form a fairly correct judgment how to proceed in development. The first box turned out all right, and I was quite charmed with the result of the entire set: but on coming to the second and third boxes, oh, what a change! No matter how I cogitated over each plate, altered the quantity of pyro, added bromide, &c. &c., it was all the same old game; nothing but flat, miserable results. No brightness or sparkle, and this notwith-

standing that my notes stated, exposed in bright sunshine. I naturally at first blamed myself, and looked around me for something that was wrong. So I gave it up, and on mentioning the circumstances to my friend, he simply smiled, and said, "Oh, I know; there were a lot of old plates as well as fresh ones." This at once solved the difficulty to my mind. I looked for no other explanation.

Now, to the bulk of the great body of ladies and gentlemen who practice photography off and on, now and again at irregular intervals, this subject must be a matter of no light importance, and it opens up a wide field for thought, if, indeed, not an entire revolution, in the manner in which plates are now supplied to the public. I am quite aware that a professional is not nearly so liable to fall into such pitfalls as one who merely now and again takes out his camera, for the professional in his constant turn over seldom or never has a supply of plates of any great age. Not so, however, with many amateurs, whose plate boxes are frequently found to contain samples of nearly every brand in the market, and of all degrees of sensitiveness. Where such is the source from whence slides are filled, in my opinion it is almost hopeless to look for any good results.

I have long since come to the conclusion that about the worst possible way of storing plates is the placing of them in grooved boxes. My experience is that deterioration soon sets in when such is the case. Another by no means infrequent cause of deterioration in plates is that which is perhaps most common of all: I refer to the practice followed by most amateurs in allowing their plates to remain in the cells of their dark slides for any length of time. It may not be known to many, but I have clearly traced a very rapid deterioration (in some instances merely a question of hours) to plates from the blacking of the slides. This, of course, is most liable in the case of new slides, or those which are freshly done up. Whenever such staining material gives off a pungent smell, beware of the evil. I have seen a plate which was not twenty-four hours in a cell that had been at the mending, and which had received new cloth hinges and blacking, show a straight line across just where it had faced this stain. For some years I have dispensed with the staining of my cells. I prefer to have them lined carefully with clean sensitised paper, which I expose to the light. I am quite sure of this, that one of the most frequent causes of deterioration of plates in the hands of an amateur, and one that is but little or seldom thought of, is this blacking of the slides. I know some samples that will spoil a plate in a few hours.

We all know how common a practice it is with many amateurs who, after being out for a time, return home with some of their cells containing plates not exposed; these remain there, it may be for weeks or months, until occasion arises for a fresh outing, then out goes the plate again, and it is expected to turn out all right. Such a practice can never yield good results. I invariably tell my pupils to empty their cells on their return home, and I know of no better way of keeping plates than by placing them face to face and storing them away in metal boxes, jamming them up with little bits of cork to keep them from slipping about. I often think were some enterprising maker to take a bold step and supply his plates to the public packed face to face in metal boxes, it would be a step in the right direction. I have travelled for over a fortnight right on end with my camera, and been jumbled up and down over some of the worst roads in the kingdom, but I never yet found any injurious results from packing my plates face to face without anything between them. Any one who knows what the packing of plates (or parcelling) entails in a dark room will at once, I am sure, appreciate any method that would overcome or avoid the trouble both of wrapping and unwrapping the plate. I see no reason, were manufacturers to make certain of the drying of their plates, to prevent them sending some out face to face in metal boxes.

I am aware a metal box is more costly than a pasteboard, but after a time these metal boxes could be returned and refilled; and, taking into consideration such items as paper wrappings, &c., I am not so certain if the cost would be so much greater after all.

As to scratching, I have clearly proved such only exists in the brain of those who speak of such an objection. For years I have adopted this plan, and when a parcel of plates is opened a gentle wipe with a soft silk handkerchief is far and away a better mode of removing any stray particles of dust, &c., than a camel's-hair brush. Plates so wiped will not scratch if placed face to face and jammed up with cork wedges.

A plate coated with a well-washed boiled emulsion will keep in such boxes with safety for a couple of years, but let the same be placed in grooved boxes and subjected to atmospheric influences, and deterioration at once begins to set in; with some brands such is very rapid.

During the course of my investigation of this subject I have from time to time come into contact with other very careful workers, and

I have been struck with their various opinions regarding this subject. In the case of one gentleman, who lives at the seaboard, and whose experience is worthy of all consideration, he declares he can get no plate to keep for over six months without showing decided signs of deterioration, but he has never tried the metal-box face-to-face plan of storing.

Another friend, who lives inland, and who has no gas in his counting house, declares he can keep Wratten's plate, if well taken care of and placed inside a tin biscuit box, for at least two years without any danger. Such quite coincides with my ideas, but I know of other brands that would not keep six weeks.

I see no reason why a good boiled emulsion that is thoroughly washed should not keep for a long time if due care be exercised in storing same.

T. N. ARMSTRONG.

REFLECTIONS ON PHOTOGRAPHERS AND PHOTOGRAPHY.

WE will begin with the assumption that people do not like to be found fault with, deserved or otherwise, and generally find some excuse to shift the blame on to something or somebody else than themselves. The old adage that "the bad workman always finds fault with his tools" is, and will continue to be, true till the end of time. This applies in a very marked manner to most of those who take up a new hobby for which their capabilities are not particularly adapted. Photography is one of those things so easy in some respects that a great majority of those who take it up consider themselves past masters in about a week, and past learning in a fortnight. The element of uncertainty—I will call it this for want of a better definition—exists in such a marked degree that it is almost impossible to say off hand if a certain fault is owing to the workman or his tools, for sometimes even after a very careful examination we may fail to draw a right conclusion.

Defects, though many and varied in character, may be roughly classed as faults in the material and faults in the user; with some that can scarcely be said to belong strictly to either category, but depend on peculiar and special conditions that cannot be anticipated. The sensitive film seems sometimes to be in that state of balance between faultiness and perfection that a slight difference in treatment will determine to one side or the other. Very highly sensitive films are often of this character, and it is with these we find a greater proportion of failures than with those less sensitive. There is no disputing that many faults are invoked by inexperience; and with regard to the manipulation of gelatine plates, from a chemical point of view, I am inclined to think that amateurs have the advantage over those termed professionals, and that instead of "amateur" being used in a depreciatory sense, and as an excuse for bad workmanship, it ought to be a term expressing a thorough and scientific acquaintance with the subject. We naturally infer that as the professional is supposed to make his income by the practice of photography he ought to know more about it than anybody else. This is, however, true only in a limited degree. The professional is eminently a "Groovist," to coin a word for the occasion, and there is neither inclination or necessity to get out of a rut that enables him to produce satisfactory work and give satisfaction to his customers—in fact, the less change the more profit. To be thoroughly master of one system is better, from a business point of view, than knowing a variety moderately well. The old professional under the new order of things is positively at a disadvantage, having to unlearn, so to say, rules and practices that have become a sort of second nature to him, whereas the amateur starts with a clean sheet, and all he has to do is to make himself acquainted with the working of dry plates that give him no trouble to prepare, and by following a few simple rules and formulæ he is enabled to produce negatives equal to those by more experienced hands—in fact, everything is so simple and so divested of trouble that he must be a very dolt who cannot produce a good photographic image, from a chemical point of view, after a little practice.

As the amateur is supposed to take up photography from mere love of the process, it stands to reason that he is free from all those obligations to an exacting public that so hamper the work of the professional. Formerly there is no doubt the art of photography required infinitely more skill—knowledge of chemicals, combined with dexterous manipulation—that could only be obtained by constant practice, so that the professional was in a much better position for producing photographic pictures than an amateur was likely to be, and his work, take it altogether (the amateur's), was in consequence inferior; there were, of course, some excellent workers amateurs, but the majority had certainly to take a back seat. The superiority of professional work in those days was undoubted and incontestable; now, however, things have changed, and the amateur, having most of the difficulties

cleared away, is certainly on an equal footing with his professional friend, if not with an advantage. Amateurs are, or ought to be, pioneers and experimenters, in contradistinction to the professionals, who carry out in the best possible manner the different plans and processes that have been discovered and utilised, rather than striking out new lines for themselves; they have their livings to gain by it, amateurs have not. This brings us on to a very delicate ground, where the two classes are unfortunately often at variance.

Amateurs, undoubtedly, fill up a place in the photographic world from which they, for many things, could be ill spared, and so long as they are contented to remain amateurs, professionals are only too glad to welcome them. It is when the professional gets rubbed the wrong way of the grain by amateurs trying, under false pretences, to make a market for their work that the grievance develops, for no doubt at the present time many businesses have been seriously injured and interfered with by the so-called amateur, who, doing very little good for himself pecuniarily, has succeeded by mere force of numbers in doing considerable harm to legitimate trade. It is the continual dripping of water that wears away the stone. It is as well to look the fact in the face, and if any can devise a remedy so much the better for everybody concerned.

There is one class of business, practically, little interfered with, and that is portraiture; and another, perhaps in a more modified degree, is copying. Both these phases of photography require a certain amount of permanent work room and a knowledge of managing the light, that, except in a few instances, is not very likely to be at the command of the amateur. But for all work where no special conditions are required, there is no reason whatever why the amateur should not produce work equal, at any rate, to that of the professional; and it would be to the credit of the amateur if he refrained from giving a systematically commercial aspect to his amusements, for although each amateur may individually make no difference, hundreds or thousands undoubtedly do.

Ordinary observation shows how extensively photography is being taken up as a hobby, and those who do so may possibly be a means of affecting some substantial good to the community at large by discovering application for the art at present unthought of. "Many thoughts, many minds," and it is to the amateur we especially look for enlightenment, and to the professional for carrying out in the best possible manner the different plans and processes that have been discovered and their usefulness indicated. So much for the workmen. We will now jot down a few stray thoughts on the materials they have to deal with.

The faults of the sensitised plates are varied, and often independent of any skill the user may bring to bear upon them, and those in best repute are not altogether at times free from reproach, although it must be conceded the great majority of plates sent out are very satisfactory, and bad plates are the exception rather than the rule. Having the opportunity of seeing the work, and hearing the remarks of many amateurs, there is no doubt that some faults which, by the exercise of a little more care, could be avoided are not so. For instance, when glass is cut too large or too small for the size it is supposed to represent, irregular in thickness, curved or rough at the edges, a great deal of avoidable annoyance and difficulty is created, and of which the purchasers have reasonable cause of complaint. Then, again, unequal coating, a fault much less frequent now than formerly, when it was a rather rare thing to get a plate with the same amount of emulsion on one end as the other, producing disastrous effects on the negative, not only in the appearance of the image, but in its permanency, the thicker portions in some makes of plates taking an unconscionable time to thoroughly fix (if they ever do get properly fixed is problematical), with the result that after, perhaps, several years of use, without showing any fault, a dark yellow-brown stain will develop, thoroughly spoiling the negative, and rendering it useless for printing purposes. There is great uncertainty in knowing when a plate is thoroughly fixed. Appearances, unfortunately, will not convey the information, the dangerous combination of hyposulphite and silver being colourless and transparent, until acted on by light or more slowly by time, may remain on the film after the negative is apparently fixed, to its ultimate destruction. Thick films that have had a liberal dose of chrome alum in their preparation are most difficult to deal with. Two hyposulphite baths, the second twice the strength of the first have been pointed out by eminent chemists as absolutely necessary to ensure the perfect removal of the hyposulphite of silver from the film, and I think we may look upon it as an established fact that the conclusion on the whole is correct. Acting on this advice the negative should be apparently fixed in the weaker bath, and then transferred for a short time to the stronger one.

Another preventable fault is caused by the method of packing thin paper of various kinds as used to place between the films. Providing

the paper was absolutely pure and of even texture, and the films perfectly dry, I do not suppose any harm would accrue, but as in many cases plates are undoubtedly damaged by this style of packing, we may reasonably infer the conditions of preservation were imperfect. Anything in partial contact with the film for a length of time is open to objection. Even if no chemical action is set up, unequal pressure may cause, by a physical alteration of the particles of bromide, marks in development. The thin card frames used by some firms seem free from objection as any, the injury, if any, being confined to the edges of the plate, and the films more protected from the action of the atmosphere than when strips are placed at two ends only. Providing the glass is quite flat, and care taken that no particles of anything hard is on the film, plates placed face to face in close contact, and kept from moving by four gummed bits of paper applied over the edges on each side, is an excellent plan, especially for the larger sized plates. But if plates are only to remain packed for a short time a piece of good white blotting paper or *papier Joseph* will, I think, not be likely to cause any faults. Speaking from my own experience, I have never found any deterioration from this method.

With regard to spotty plates which, if not home made, are beyond the control of the user, the fault is probably induced by the use of an unsuitable sample of gelatine, or imperfect filtration of the emulsion, or some error in mixing. Dark lines or insensitive patches may generally be traced to some oversight in the preparation of the plates, or, in the case of dark lines and marking of this character, to abrasion of the surface of an otherwise perfect film. A gelatine-plate manufacturer once told me, when I complained of finger marks on his plates, that it was almost impossible to get the work girls to be sufficiently careful when not being watched. This was perhaps true in that particular instance, before the improved methods of coating and storing plates in vogue at the present time were adopted, but now plates of the present day are, as a rule, very free from faults of careless manipulation. Fogged and defective plates have undoubtedly been sent out from the makers for which there is no excuse, such action being calculated to produce considerable loss and vexation to the users, there being no means whatever of providing for such contingencies or remedying the defects.

I believe all makers of reputation at the present time test every batch of emulsion made, as it is evidently to their advantage to put plates perfect as possible in the market, and, take them all round, they succeed very well in their endeavours, sensitiveness being the quality in which they most vary; but the mode adopted of expressing the rapidity of plates is somewhat bewildering, "so many times" being the stock phrase. So many times more rapid than wet plates is of course inferred, but as the sensitiveness of wet plates is not a constant quantity, it is but little guide in that respect. Moreover, the majority of users of gelatine plates in the present day probably know little or nothing of wet-plate practice. It is time some other mode of expression was adopted that would really indicate the different rapidities in a rational manner, which is far from the case at the present time. A matter so important as exposure—the principal element of success in a good negative—ought not, for the credit of photographers, to be dealt with in so absurd and childish a fashion. The Warnerke sensitometer has been the best available guide at present, but a far from perfect one; still, by quoting such a number "Warnerke," a better idea is conveyed of the rapidity of a plate than by the "so many times," which conveys no idea at all, except an erroneous one. Photographers, look to it!

Wrong exposure is one of the principal causes of faulty negatives. The forced development of an under-exposed negative will bring out faults that would, with a proper exposure, have remained unnoticed even if latent, and, at the best, such negatives are always deficient in quality, or the power of producing rich, solid prints, no matter how carefully and skilfully they may be printed. It will be seen that the lights are harsh, and there is a want of detail in the shadows, and the connecting half tone is poor, and sometimes altogether absent. Over exposures are more easily dealt with, and, in many cases, the development can be restrained so that a good negative is the result, but much depends on the character of the film. An exposure that has produced a reversal of the image cannot be treated satisfactorily. Some emulsions are more prone to this than others, and the image will become reversed with an exposure that would not affect another make of plate in the least; in fact, some are so sensitive in this respect that a view that has received generally a light exposure will have the highest lights reversed, or very thin and flat. This tendency to reversal is a very grave fault, as undoubtedly the whole of the image is prejudicially affected, although it may only be detected in certain parts as interfering seriously with the printing qualities of the negative. A proper exposure will, on a good plate, produce a perfect image with a minimum of trouble; the intensity will be right, the shadows

clear, with plenty of printing detail, no chalkiness in the high lights, and the prints from it will be rich and harmonious in all respects.

Streaks and mottling are sometimes produced by imperfectly mixing the developer or by holding the negative up to the light to judge of the intensity, especially in the earlier stages of the development, or by letting the plate remain still instead of rocking it during the process. If horizontal baths are used, the solution should always be kept in motion whilst plates are under treatment, whether it be the developer alum or hypo, or the probability is there will be markings on the negatives. The old vertical dipping bath is much the best for both alum and fixing solutions.

To those who have had but little experience in development it is most difficult, if not impossible, to correctly assign the effects to proper causes, especially as similar defects are produced by very dissimilar causes; and it is only by keen observation and practice that the right reasons are discovered. A very slight difference in modes of manipulation will result in success or failure. Another fault is "green fog." This is a questionable fault, as it may be avoided by the use of fixed alkalis in the developer in lieu of ammonia and ammonia compounds, which seem to induce a precipitation of silver throughout the film, and thus produce the fog. A first-class negative may be made by using soda or potash, that with ammonia as a developer would be utterly useless. Insensitiveness, beginning at the edges of the plate and gradually working inwards, is generally caused by the action of impure air or gas on the films. Plates stored away and imperfectly protected are liable to this fault, especially if they are very sensitive films. Sometimes the insensitiveness shows itself in patches all over the plates; at other times plates develop with excess of density at the edges. This is probably caused either by some small amount of light having acted upon them as they are packed together, or by something deleterious in the strips of material used to keep the plates apart. The spreading of these defects depends very much on the character of the film itself. Probably in bad cases the emulsion was insufficiently washed.

To preserve a dry plate for a length of time, it is advisable to keep it perfectly dry and protected from the action of the air. A good plate then will keep indefinitely. It is a dangerous practice to keep plates in the dark slides, as several possible sources of damage are risked—exhalations from the varnish, wood, or leather; dust, and free access of air. It is possible to keep plates so uninjured, but the risk is considerable. As to faults on the plates from the light getting to them from defective camera fittings, the cause suggests the remedy, although some leakage of light may exist a long time without being suspected, the focussing cloth, or something else, accidentally remedying the defect during exposure. We may pay especial attention to the corners of the bellows, the fitting of the flange to the front, or some nail or screw hole insecure. In the dark slides the fitting of the shutter into the frame, or, with the cheaply made ones, the giving way of the corners, are likely to cause trouble; for, bear in mind, a very little chink will let in a very great deal of light, if not directly on to the plate, by reflection. How important the total exclusion of light, other than that which passes through the lens to form the image, is, may be emphasised by our knowledge of the fact that a pinhole scarcely visible to the unassisted sight, in fact quite invisible unless searched for specially, will form a developable image on the plate in a comparatively short time, or by acting at the same time as the lens produces fog over the whole or part of the plate.

These rambling remarks are not strung together with any idea of novelty, but merely to hint at the probable cause of certain defects and failures that must be more or less familiar to all those who "go in" for this pleasant hobby—Photography.

EDWARD DUNMORE.

PHOTOGRAPHIC USES OF URANIUM.

IV.

THERE is occasional allusion to the fact that the uranium salts may be used to tone albumen-silver prints, but practical experiences of the method are seldom forthcoming. The nitrate, with potassium ferridcyanide, is, as we know, suitable for augmenting the deposit of the negative, and for changing the appearance of positives obtained by development, and there is some reasonableness in the suggestion—for such a method has never clearly held a specific place in the photographic formula—that this, or another uranium salt, would prove of service in determining the final colour and constitution of the printed albumen-silver positive. Besides gold and uranium, platinum is sometimes briefly mentioned as being serviceable as a toning agent. The process is not, and never was, largely adopted, the principal reason adverse to it being probably that the deposition proceeds with extreme

slowness and perfunctoriness. This difficulty of tardy reduction is not experienced with uranium.

It will be plain that, if in any attempt to modify the printed silver picture it is considered essential to reproduce the familiar *rationale* of the gold-toning process by another agency, a salt having chlorine in its combination must be selected. Of the uranium compounds, the oxy-chloride ($U_2O_2Cl_2$) is a body having claims to notice on that ground. The necessity for adding an alkaline compound to the uranium-toning solution exists as in the case of the gold chloride, although it is a moot point whether an acid solution might not be taken. In the old platinum-toning process acidified and alkaline solutions are said to have yielded respectively black and brown tones, but, as a fact, the latter kind were rarely employed, and consequently the resultant tone of the platinum-treated silver prints was invariably black. The distinguishing feature of uranium as a toning agent is that in deposition upon the silver image it imparts a cold black hue to the picture, which, as metallic uranium lends itself to considerable alteration of colour, may be appreciably varied by other alkaline substances.

According to some of my own experiences, uranium nitrate also appears suitable for employment in the toning of albumen-silver prints, although this is in disregard of the theoretical considerations dictating the use of the chloride. A mixture of two grains of uranic nitrate and ten grains of potassium carbonate in ten ounces of water is a solution of convenient strength. The most marked results seem to be obtained if the print is only moderately well washed. The toning action proceeds as rapidly as with gold, and may be carried to a considerable depth; the pictures acquire a cold black colour. With other alkaline agents, variations of tone may be obtained as mentioned above. Silver images on plain or matt paper are, however, more agreeably influenced by uranium toning than those formed on an albumenised surface; indeed, from the kind of picture so produced, it would point to the absence of the albumen as affording the best conditions for the employment of a toning agent conducive to the cold non-glossy effects largely favoured at the present time. Obviously, any expression of opinion upon the stability of silver images so treated would be pure guess work. It is, however, not difficult to understand that the displacement of gold by uranium for toning purposes cannot, on grounds of theory, be recommended, while the whole matter of the comparative permanence and longevity of photographs is ill-defined. A great deal of what has been said on the subject is mere speculation, too often biased and partial.

The line of analogies that may be instituted between the properties and reactions of many of the substances used in photography is of interest from several standpoints. This is particularly to be noticed in the case of the ferric and uranic compounds and their derivatives. The similarity of the higher uranium and iron bodies as temporary image-forming agents is the subject of common remark, and has already been glanced at here. There remains a comparison of interest that may be made between the ferrous and uranous compounds, although it belongs less to the realm of certainty than to that of conjecture. I will try to give expression to it.

Ferric oxalate, $Fe_2(C_2O_4)_3$, by its sensitiveness to light produces ferrous oxalate, FeC_2O_4 , which, among other characteristics, has the power of reducing certain silver salts to the metal, notably the sub-salt of the latent image formed by exposing the bromide to light. Let us turn to what may be called the corresponding uranium compound. The per-salt, the nitrate $U_2O_5(NO_3)_2$, is acted upon by light, being changed to uranous oxide, UO_2 , which has the property of depositing the metals silver and gold from their salts. The point I desire to underline is the likelihood of uranous oxide, in addition to depositing silver nitrate, carrying on the resemblance to ferrous oxalate to the limits of completion and reducing silver sub-bromide. I consider the inference to lean to an affirmative answer, although I am at present unable to sustain the argument by any other evidence than simple deduction. I would, however, premise that these and the preceding notes of the subject covered by the title of the present series of articles were made in the latter part of the past winter. Since then I came across a fragmentary reference to a statement, bearing the authority of the late Dr. Van Monckhoven, that "the latent image can be developed by salts of uranium." Granting that this can be subjected to conclusive proof, I should support the supposition that an oxide is the active reducing agent referred to. The term "salts of uranium" is, in this sense, a vagary; none of those in the ordinary channels of commerce "develop" (reduce) the haloid silver salts. I find no record of a uranium oxide ever having been employed as a reducing agent; but, passing over my own conclusions, the weight and esteem of Monckhoven's statement is too great to be seriously doubted, and while awaiting an opportunity of confirming or negating the theory, I will shelter myself behind his

authority, and assume the completeness of the analogy between the ferrous and uranic compounds.

Among early adaptations of the uranium salts was Colonel Wortley's modification of the collodio-bromide process, in which uranic nitrate was added to the emulsion, and was said to assist in imparting an increase of sensitiveness. The same principle was, I believe, utilised in the gelatine process. From this and what has gone before, it can be seen that, commencing with the constitution of the sensitive film and finishing with the positive impression, the uranium salts have at different times played not unimportant parts in the operations of photography. The chemistry of those bodies has never been fully expounded, and it may be that to this cause we are to attribute the curiously incomplete manner in which they have been handled by the experimentalists. Very likely they would well repay for the diversion of a little of the attention that is now bestowed upon subjects that are getting tediously over discussed. An enumeration of the many uses to which, despite our imperfect knowledge of their properties and capabilities, the uranium salts may be put, should alone fortify the opinion that we have much to learn in those regards.

THOMAS BEDDING.

LIGHTING THE SITTER.

IV.

THE best method of applying curtains to the side light or casement is to have two curtains, preferably of a dark blue material, hung with rings on a brass tube or wire stretched at the upper end of the window. When these curtains are fully drawn they will meet in the centre, completely covering the glass, and their length will, of course, be a little longer than the height of the window.

If mirrors are applied outside the casement, it will be desirable to have a second blind of thin white calico hung on a separate wire stretched parallel and near to the wire supporting the dark blue curtains. It often happens that a weak diffused light is wanted from the direction of the casement, and this may be obtained by drawing the white blind across the glass instead of the dark blinds. If preferred, the white blind may be fixed to a spring roller at the upper end of the casement. This would be a neater arrangement than having it hanging loose.

Having now discussed the details of the walls, the ceiling, and the windows, we come to the floor. This is a very important point, as it is the proper place to put the reflector of the skylight. If the floor is covered with white paper it will be impossible to get strong shadows on the face, however we may alter the lighting: while, if the white paper is replaced by dark oil cloth the shadows cast by the top light will be too dark. With the side light on the one hand, and the reflecting blinds on the other, we can soften these shadows, but still it is not the best way to proceed. We should always try to have the reflector opposite the main light, and when the lighting is from above, it is obvious that the reflector should be on the floor.

It is not much use relying upon an oil cloth printed in light colours on the surface, as the paint soon wears off or becomes discoloured. As a rule, the design is of a red or yellow cast, and is useless for reflecting purposes.

As we cannot conveniently make a fixed reflector of the oil cloth, we must use instead adjustable white coverings to lay on the floor when required. White wall paper is both cheap and handy; when it gets soiled by being walked upon it is not a ruinous consideration to have it replaced. White calico sheets, stretched on light lath frames about two feet by four, are convenient, and can be washed or brushed occasionally.

A reflector of white paper or calico a yard wide, stretching across the floor of the studio just in front of the sitter, has a wonderful effect in softening the shadows cast by a strong top light.

Studios surrounded by buildings, and which are said to be "down in a well," will find these floor reflectors very valuable. They have a marked effect upon the expression, which is apt to appear too heavy and careworn with a strong top light; to soften the expression we must first soften the shadows.

In laying these floor reflectors we must take care not to bring them too far in front of the sitter, or they will produce false lights in the eyes. A safe rule is not to bring them further forward from the sitter than the height of the sitter's face above the floor. Thus, with an adult standing figure, the edge of the reflector nearest the camera should be within five feet of the heels; with a sitting figure the limit will be about a foot nearer the background.

When "instantaneous" portraits are taken in the studio of babies, kittens, dogs, and other subjects in which the problem of perpetual motion seems to be solved, we can shorten the exposure a good deal

by using plenty of reflected light. The maxim of exposing for the shadows and leaving the high lights to take care of themselves is a good one; so, to shorten the exposure we must increase the lighting of the shadows. With the full power of the skylight and mirror-fitted casement, and with the assistance of the reflectors on the floor and the side wall, we should be able to shorten the exposure almost enough to render the drop shutter necessary.

In large studios, where the skylight has a considerable area of glass, it is found convenient to have a small screen or two placed half way between the glass and the sitter; this small screen will produce the same effect on single figures as that obtained by the use of blinds four times the size placed close to the glass. The latter would, of course, be required with large subjects, such as groups.

The small screen has an advantage over the large one; by its use it is easy to increase or reduce the light falling on the sitter without interfering with the lighting of the backgrounds; by this means we can to a certain extent make the background light or dark at pleasure.

A convenient and simple way to fix these small blinds—one which can be applied to any studio—is to fix six or eight screw eyes or screw rings into the wall just over the background, and then fixing a similar set of rings to the opposite end of the studio, behind the camera, at a like distance from the floor. A quantity of ordinary copper bell wire being procured, we can proceed to stretch it from one end of the studio to the other by means of the screw eyes. We shall then have six or eight parallel wires running overhead the full length of the studio. If the studio is long, it will be better to have a horizontal cross bar of wood in the middle, running from the casement to the opposite wall. The screw eyes can be fixed to this bar, and the length of the wires necessary will be thus greatly reduced, as they need only extend the length of the skylight.

We may next make two or three very light wood frames about four feet long and two wide; upon each of these we can stretch or pin a piece of white calico or paper. These frames will then rest by their own weight upon the wires, and can be placed in any position by a touch with a walking stick; or, if short lengths of string or wooden laths are fixed to the frames, with the ends hanging loosely down within reach of the hand, the stick will be unnecessary.

The system is so simple and inexpensive that it ought to become popular. By its use we have perfect control over the top light. The white paper screens will cut off sufficient light for most purposes, while, if greater opacity is wanted, it is easy to use brown paper instead of the white.

The light-framed reflectors made for the floor will answer also for the overhead shades; but as they may be wanted in both places at once, it is advisable to have three or four of them.

When outdoor portraiture is being undertaken, and there is no means of cutting off superfluous top light, we can prevent dark shadows being thrown over the eyes and under the chin by the use of reflectors on the ground. We may get these by placing the sitters upon or behind a light stone pavement; or, in default thereof, we can spread on the ground some light material, such as two or three yards of white calico.

These reflectors need not appear at all in the photograph, even with a full-length portrait, but care should be taken not to bring them too far in advance of the sitter.

This series of articles may be concluded with a final hint, which will be useful when persons with dark-brown or black eyes are being photographed. In such cases the iris is apt to appear as dark as the pupil. By arranging a large white screen of the same shape as the light patch which indicates the iris, we can put it in the proper angle of reflection, so that its miniature image will appear on the iris when viewed from the camera, and will photograph exactly as if the iris itself was the source of the little bit of light, or, rather, half tone.

The shape of this iris reflector may be a crescent, the outer edge forming a two-thirds segment of a circle, the diameter of which is equal to the distance—five feet, for instance—separating the crescent from the sitter. The horns and edges of the crescent should be shaded off with grey pigment, so that the shape of the reflection in the eye will appear somewhat ill-defined.

When in use, the convex side of the crescent should always be opposite the chief light, or, in other words, the two horns of the crescent should point at the light. If the skylight is the chief source of illumination, the horns will point upwards. If the top light is screened off, and the side light used instead, the horns will both point horizontally at a point half way between the camera and casement. If the sitter is looking at the camera, the crescent will be placed between the two. If he is looking at a point three feet to the right of the camera, the crescent will have to be put on the same side with its centre at double this distance from the camera, viz., six feet.

The crescent should not be used with light eyes, as its use would

be detrimental to the photograph; but with dark eyes it is an advantage, as it apparently brings out the detail of the iris. It should be illuminated strongly, and is, of course, only effective when the studio wall behind it is dark.

ALBERT W. SCOTT.

AN EASY METHOD OF DETERMINING THE RELATIVE SENSITIVENESS OF PHOTOGRAPHIC PLATES.

WHEN a photographer has purchased three brands of plates marked 60, 35, and 26 by their respective makers, he not unnaturally may wish to know which is really the most sensitive. He can readily settle the question to his own satisfaction, however, without any special apparatus, the first clear evening. Let him focus his camera for parallel rays by daylight; the larger and longer focus his lens the better. When night comes on point the camera on the pole star by sighting along its edge, as one might sight a rifle. This is necessary, as the stars are in general too faint to be seen upon the ground glass. Care should be taken that in this position the plate remains perpendicular to the axis of the lens, as some cameras are liable to bend when inclined. This difficulty may be overcome by resting the camera upon a board. One should use the full aperture and give an exposure of about ten minutes. On developing, numerous stars will be found which are invisible to the naked eye. The stars will all leave trails, forming arcs of concentric circles whose centre lies near the centre of the plate. The plate should be given full development, as nothing will be seen upon it until it is fixed. Since the stars are in constant motion, the intensity of the image is independent of the exposure, which effects only the length of the trails. To obtain a good stellar photograph, much more accurate focussing is required than for ordinary views, and it may be necessary to take two or three plates, varying the focus slightly in each case, before the best result is obtained.

In general, a photographer wishes only to know which of several plates is the most rapid. To this end they should be exposed immediately one after the other, and then each developed according to the printed directions accompanying the box. The experiment should be repeated two or three times in order to ensure the greatest certainty in the result. The most accurate way of comparing the plates is to cut a circular hole one inch in diameter in a piece of paper and hold it against the back of the plate, so that the pole star shall be in the centre. The pole star may be recognised as a black, somewhat elongated dot near the centre of the concentric arcs. Now, with a pocket magnifier, count all the stars visible through the hole. The plate showing the most stars is the most sensitive. It is well to count them over two or three times, as if there are many it is at first difficult to make them come out twice alike. A difference of five per cent. in the total number of stars shown by two plates would make very little difference in their relative sensitiveness.

If it is desired to find out how many times more sensitive one plate is than another, one must vary the aperture of the camera lens by paper stops placed in front of it, until the same number of stars are shown in both cases. The relative aperture of the stops then give the rate of sensitiveness of the plates.

—Anthony's Bulletin.

SILVER PRINTING ON ROUGH DRAWING PAPER AND OTHER SURFACES.

AMONG the many processes which have either been forgotten through want of persistent keeping before the public, or by reason of not being taken up as a trade matter, or from other causes, but which remains in a state of suspended animation, is that of the proper way of printing on rough drawing paper. The subject was written of a few months ago in a contemporary journal by Mr. H. H. Biggs as a new thing, and had it remained there unnoticed, it is probable that it might have been left in its comparative obscurity; but when our eminent friend, Dr. Ellerslie Wallace, of the *American Journal of Photography*, takes up a similar rôle, as quoted in page 474 of this JOURNAL, it is time, and there is reason, in calling attention to the subject, more especially as neither of these gentlemen have, to use the vulgar expression, "got the right sow by the lug." The first-mentioned writer simply advises sizing the paper with a four-grain solution of gelatine, salted with five grains sodium chloride to the ounce, and sensitising it with a sixty-grain solution of ammonia nitrate of silver made in the usual way, and coated by brushing with a Buckle's brush, then to be printed deeply, and toned and finished as usual.

Dr. Wallace, writing of this, takes a broader view of the subject, and

looks more at the qualities sought for by using the rougher and matt surface papers together with the artistic advantages to be derived by using this and similar processes which give effects that cannot be got by the use of albumenised and other glossy surfaces. There is one point, however, of which no notice has been taken by either of the gentlemen mentioned—i.e., the permanency of prints on plain as compared with albumenised paper, a truth which is now accepted almost without question. The most cursory examination of silver prints taken from the same negatives by the same persons five-and-twenty or more years ago, whether kept in frame or folio, or mounted in book form, will show the better keeping qualities of the plain paper print. In the latter way of keeping prints I notice that the fading, where there is any, is always at the edges, where the effect of the mountant is often visible in a distinctly faded external edge, the print being attached to the book mount by the outer edges only in the cases quoted, and almost always unfaded in the centre of the print.

But there has been found by workers with plain paper a peculiar difficulty in preventing the print having a sunk-in appearance, and combined with want of vigour as compared with those on the albumenised surface, which no doubt accounts for the comparative disuse of the really more artistic prints on the plain paper. About the period alluded to a pretty exhaustive series of experiments were entered upon and carried through with the view of finding a method of keeping the image more on the surface of the paper, and giving it, while keeping the matt surface intact, more of the brilliancy and power of its rival. In the earlier days the selection and choice of papers was a most important matter, but choose which one might, as they were all prepared pretty much in the same way as that indicated above, with the difference only of using plain nitrate of silver solution instead of the ammonia nitrate, the latter not coming into general use for some time later, the outcome was sometimes most tantalising, the differing samples of paper behaving in very diverse ways, and generally diverse to the way that was wanted. This series of experiments led to the proposal of a system for preparing the surface of any kind of paper so that it would accept the sensitising medium and keep the image on the surface, thus showing the same vigour without having the meretricious gloss of the albuminous print, and without its inherent elements of decay. The method was known and named, as everything was then named, a process—the "Ormolu" process, from a technical trade term, the emulsion used for preparing the paper bearing that name, and one form of it being used for a very different purpose.

In simply sizing with gelatine the surface of drawing or such-like papers, the image, as previously stated, will seem to enter into the body of the paper, so much so, that with some of the thin papers the photographic picture seems as if it were brighter when looking at it as a transparency with a good light behind it than when looked at on the surface. By this Ormolu process all kinds of paper may be used for photographic printing purposes, whether made with that intention or not, from the thinnest to the thickest, the most highly glazed to the roughest hand-made writing papers, and any kind or sort of drawing paper, from Whatman's best to the cheapest cartridge, and in addition crayon papers of all shades, as well as all the softer papers, are as amenable to photographic uses as are the best Rives or Saxe; indeed, there were exhibited, the last time it was publicly spoken about, pictures upon the lithographed backgrounds of Sarony, on the backs of theatre and circus posters, and on all kinds of common wrapping and brown papers, which were perfect in all photographic respects. This method, however, will not prevent the appearance of such accidental imperfections as are caused by the minute atoms of brass, copper, or iron which get embedded into the substance of all papers in greater or less numbers, according to the care in the preparation, the perfection of the machinery, and other factors of that nature; but it seems proof against all others, so far as has been experimented upon.

For the corners of handkerchiefs, silk or linen, it is perfection when the material is used very thin, and on the tops of note paper many a dainty little negative can be printed with the greatest of ease and almost without soiling the fingers. One great advantage this system possesses over simple gelatine is that by being emulsified it becomes much more insoluble, and so assists the paper to stand the washing better, in addition to the more valuable property of keeping the image on the surface.

In preparing the emulsion we will consider the gelatine first. Of course there are many varieties of this substance, some being more suitable than others, and that which takes the first place in this process is known as gilders' clear size, which is made by boiling, or rather simmering, cuttings of parchment or vellum, or of untanned buffalo hide, &c., all of which substances are sold for this purpose. In great cities, such as London, the size can be purchased ready made. Next to this may be placed the ordinary calf-foot jelly for table use, but without colouring or spicing of any kind. This last may be taken

as the proper strength of gelatinity to use for this process. In making use of either of these varieties, there seems to remain in the substance of the gelatine a portion of animal oil, which, if not essential, is at all events advantageous, so much so that in using the commercial gelatines, which are so treated in the preparation by exhaustive bleaching with lime, &c., that all the oily matter of the hides from which it is extracted is destroyed, it is desirable to add a minute portion of oil to the emulsion, as will be pointed out further on.

In using commercial gelatine it may be well to note that all samples are not of the same strength as it is called; for instance, tradesmen in using glue know that the best Scotch or Russian is almost infinitely stronger than the cheaper English and French examples, although the latter may look even better. Ask a bow maker or a pianoforte case maker to use the latter-cited kinds, and he would laugh at the idea. So it is with the commercial samples of gelatine, and that is why the preference is given to the strength of the solution rather than to the weight in grains or ounces, as five grains of one kind may be worth ten of another, which, while quite as good for the purpose for which it was made, has not the same amount of gelatinousness in it.

With these preliminary observations it may be said that the best way to proceed, if gelatine be used, is to place in an earthen or glass jar—such as a Liebig's essence one, or of that shape—as much as will half fill it of the shreds, or if the material is in cakes then break it finely down in a cloth or strong paper; cover it, when placed in the dish, fully with water and allow to remain for three or four hours, or till it has absorbed as much water as it will. Then pour the water off and add as much fresh as will just cover the swelled mass; afterwards dissolve or melt by heating, but do not raise the heat above about 180° Fahr.—it is injured very much in its properties by being overheated; a warm water bath similar to a glue pot is the proper thing to use; then allow it to cool and set, when the strength of the jelly will be seen. If too strong add a little water, if too weak a little more of the dry gelatine (this really is a matter of judgment). For convenience this may be called solution A.

In the interim this may have been got ready. Make a solution of any of the under-mentioned gums in methylated spirits of wine of not less than 60 per cent. o. p. It would be of little use putting the specific gravity, as this is the method of describing it, on sale or purchase, and these remarks are meant as a practical help for common use. Shellac freshly bleached stands first. If this substance is kept long, by exposure to the air it becomes oxidized and insoluble, which is easily seen by breaking the stick (it is sold in sticks) across, when, if it is old, the external crust will be found to have become yellowish, and the further this extends inwards the more useless is the sample, and therefore to be avoided. Next in order and usefulness is gum sandrac, which is like the bleached shellac—a nearly colourless gum. Gum benzoin has much more colour and is altogether not quite so useful for this purpose, but it does. Gum mastic does exceedingly well, but it is difficult to dissolve wholly in spirits of wine, and this combined with a high price will prevent its common use. The palest orange lac will also do, the only objection to it is the slight colour it necessarily has, otherwise it is the best.

To make use of the lac or benzoin they must be pounded into a coarse powder, the sandrac and mastic are in the form of tears, and need nothing of that nature; but with either of them it is well to add about the same bulk of coarsely pounded glass, which keeps the gum from agglomerating and forming a sticky mass difficult of solution, and this, when the gum is dissolved, falls to the bottom with the dirt and insoluble particles and does not affect the result. In this connexion the longer the solution is kept, and in full light, the brighter and more colourless it becomes without affecting its other properties. If this has to be used with the commercial gelatines it is well to add a drop of castor oil, which mixes easily in the spirituous solution, to each two ounces of it; this will make the gelatine act more like the clear size in the making of the emulsion and so render it better.

The proportions are about one ounce of either of the gums to eight ounces of methylated spirits, which, after being made as described, may be called solution B; it is better after it has deposited all the dirt and insoluble matter to filter or decant for use. The proportions given are not hard and fast, a little, more or less, on either side does no appreciable harm.

To make the emulsion melt the gelatine, as directed, pour as much of B gently into A, with stirring, as will give it the colour and appearance of cream. There will be a deposit of gum in most instances, caused partly by the difference in strength of the gelatine, and partly by the proportion of gum being perhaps too great; in fact, it is a very rare occurrence that the emulsion is completed without this deposition.

Add now from four to seven grains of sodium chloride or ammonium chloride, as the operator may wish to use. The potassic chloride has been found unsuitable. The salt should be dissolved in a few drops of warm water and added to the emulsion, then filter through fine muslin and it is ready for use. In coating the paper a camel's-hair flat brush may be used, but perhaps as handy a way is to use a fine small sponge, spreading it in all directions until the paper has absorbed the necessary amount, which will be ascertained when it shows equally wet or rather damp all over and without any portion being unduly flooded.

This treatment relates to the firm-bodied, well-sized drawing papers with rough or smooth surfaces, as prepared and made specially for water-colour painting; but in dealing with the softer papers, such as those used for copper or steel-plate printing, or the toned papers used for crayon drawing and such-like purposes, a slightly different treatment is necessary, they being so slightly sized as to be in some instances little, if anything, harder than blotting paper. Crayons may be first considered, as photographs are frequently wanted to be as like them as may be—indeed, a life-size head printed on crayon paper and well finished by an artist's hand is better than nine-tenths of the portraits which pose as fine crayon portraits by gentlemen with half an alphabet after their names. In printing a life-size head, whether taken direct or with an enlarged negative, it is found that after being prepared, printed, and finished in the ordinary way, that the surface of the paper has been so destroyed that it will no longer take the crayons hard or soft, that the paper has lost its tooth, as the phrase goes, and even with the preparation by this method the result is similar; but there is a way out of the difficulty which has proved satisfactory, and it is this: Instead of using the full strength of the emulsion, as in the previous case, add about one-third of water to it; then, in addition, add the proper proportion of salt for the added water, and give the paper when it is melted and mixed a first coat in the manner described, but without allowing it to soak so thoroughly into the body of the paper as has been directed. It may then be hung up to dry anywhere or how, but preferably over a rod or stretched cord. When quite dry give it a second coat of the same, and dry it flat, as directed afterwards, if there are several sheets; but if there are one or two only, a good way is to fix them on a drawing board with a few tacks or pins, just as a sheet of drawing paper is put down for sketching upon. If the photograph is of the head and shoulders vignettted, the position being arranged, there need be no more sensitised than the required portion, the ammonia nitrate being used in this case, but let the tyro beware and not do the same thing with the emulsion sizing, as if that is partially done the sheet of paper will be utterly spoiled.

After the printing and washing is finished, which is all done in the ordinary way, the toning need only be carried as far as it is desired that the finished chalk should be in colour, and after the completion of the fixing and washing, the question of the restoration of the surface of the crayon paper, so that it may take the chalk as if it had never been interfered with, arises. Fix on a board with blotting paper below it, and with a sponge go over it with a weak solution of ammonia, but avoiding the printed part, which should be kept damp, or but slightly touched with the ammonia. Allow this to sink in, then press the damp sponge over the surface, removing as much of the sizing as the alkali has softened; then, after the full effect has resulted, take hot water and sponge over and over, dabbing with the fine sponge to extract the softened sizing without breaking the surface of the paper. This, if deftly and skilfully done, will leave the sheet pretty much as it was before printing the photograph upon it. If, after being dried flat, as indicated further on, it should be found that it is a difficult matter to get the chalks to bite, a usual expedient is to go over the whole surface very lightly with a piece of the finest glass paper, known as flour paper; this, when carefully done, dusted off, and finished with a rub with a piece of uncoated paper of the same kind, will at once create the necessary tooth for the crayons or pastels, and so enable the picture to be artistically finished. The operations may seem tedious and lengthy, but in reality they are very rapidly got through; it is the description that, to be accurate, had to be protracted.

The whole operations of sizing with the emulsion, and everything but the drying and keeping of the prepared papers, should be done in a place as free from dust as possible, and in daylight. When the sheets are about three-quarters dry, they should be placed one above another, face to face, and back to back, and the prepared side should be marked with a pencil to prevent mistakes; when all are piled up, place them on a flat board with blotting paper below, and above them another similar board with a light weight on top, in which state they should be allowed to remain till quite dry.

Dr. Wallace lays some stress on the fact that albumenised papers

expand and contract irregularly, this is caused by the strong contractile power of the albuminous coating which is on one side only; but it is a fact that all papers which are machine made have a fashion of expanding more one way than the other when they are damped. Hand-made papers have not this peculiarity, as they stretch equally in all directions; as he makes no observation on this point, he may not have noticed it.

In some of the more recent experiments there has been added, to increase the insolubility of the emulsion, about a grain of chrome alum to the ounce of emulsion, but without appreciable effect, and printing on crayon paper it should not be used. In sensitising the paper, which will be found perfectly flat after the treatment prescribed, this may be done in the ordinary way by floating on a sixty-grain silver bath, or if the paper be of a strong kind, like Whatman's heavy drawing, it may be made into a bath by pinching the corners with clips, or by using for the same purpose strong mourning pins, the black japan varnish protecting the solution from all injury. Of course, the sheets may be fumed or not at pleasure. If the ammonia nitrate sensitiser be preferred in coating it, I like a fine small sponge (kept for the purpose), as in the case of the emulsion, as it seems in the crossing and recrossing to prevent any of those white lines which sometimes will appear when using a camel's-hair or a Buckle's brush. The rest of the treatment is precisely as for ordinary photographic printing as to the toning, fixing, and washing, but in the final drying, while treating them as recommended during the coating with emulsion, it is well to interpose blotting paper between each printed sheet, and the result will be found to be a perfect success in every quality which a print should have if the directions have been carefully attended to and the negatives what they ought to be, and they will be as flat as a steel engraving, and flatter than many water-colour drawings.

A very beautiful and effective way to treat large views or copies is to so mask the negative and drawing paper as to get the picture in the centre of the sheet with a margin of three or four inches all round; the effect will be found to be very agreeable and artistic, while costing very little trouble.

W. H. DAVIES.

THE BEACON ON MEN AND THINGS.

WE extract from Dr. John Nicol's *Beacon* the following somewhat strongly expressed jottings on things European, to show in what estimate our Chicago friends hold them:—

W. J. STILLMAN's ideas of "art in photography" are, as most students of the literature of photography know, rather hazy, and, when clearly expressed, lean strongly to the nonsensical side. According to his confession of faith, the artistic qualities of photography are to be sought for only in the perfection of its technical qualities; and, therefore, all the art to which photography is capable of giving expression may be found even in the ridiculous positions so often assumed by popular actresses, as if they were merely lay figures twisted into grotesque attitudes, on which to display fancy costumes, so long as something approaching technical perfection has been reached. No doubt this view of the question is flattering to those of the fraternity whose soul cannot soar above the merely mechanical, but their faith ought to be shaken in Mr. Stillman as a teacher when they read what he gravely tells us, in a recent issue of a contemporary, is true art and what is not.

The article is too long and too weak for quotation, but the gist of the matter seems to be as follows: According to this teacher, legitimate art is "design," and design does not consist of thought and plan and arrangement, of the conception of a work of art in fact, but in the transferring of it by brush or pencil to canvas or paper. In case this should not be clear enough, he illustrates and enforces his views by mentioning two prints, each equally good and beautiful—the one a photograph from life, the other a copy of a picture. He says that the print from life might, in all its essential qualities, have been from a picture, while the print from the picture might equally have been from nature, and that then their position in respect to art would have been reversed. In short, according to Mr. Stillman, it is not perfection in composition, and light and shade, and the possession of good pictorial qualities generally, that entitles a picture to be considered a work of art, that coveted title being only legitimately bestowed on work turned out in a particular way.

AMATEUR photographers have need to pray to be delivered from their friends, and especially from the well-meant but very questionable advice of Laura M. Marquand in a recent number of *Science*. If her mission was to make manikins in art she couldn't adopt a better method of teaching. It is, get a hold of all the "masters" you can, both ancient and modern, and copy, copy, copy, imitate, imitate, imitate. Don't let slip a light or shadow, and be sure you get every article of dress right. Oh, Laura M. Marquand! you don't know how much harm such advice would do if the rising race of amateurs were to adopt it; but your concluding paragraph is comforting. "This is a branch of photography which has been but little attempted." Let us be thankful for

that, and pray that long may it so be. The "masters," both ancient and modern, are invaluable as studies or educational agents, but the mind that can be content to merely copy and imitate is very small to begin with, and will soon dwindle into something smaller still.

STRANGE things are sometimes seen from the watch tower, but nothing stranger for many a day than the Emerson squabble that has been going on in some of the English photographic journals. Dr. Emerson is a young man of considerable ability, but possessed of much less than the average amount of wisdom, and his book, *Naturalistic Photography*, is made up of good and bad in something like the same proportion. Because some of his critics have honestly said so, the doctor has treated them to a column and a half of senseless abuse that must be the envy of every Billingsgate fish-wife. "Liars," "lying cowards," "stupid fools," "ignoramus," are a few samples of the choice vocabulary of the gentlemanly doctor.

THROUGH JAPAN WITH A CAMERA.

CHAPTER VIII.—SHIRAKAWA—THE TOTAL ECLIPSE—A JAPANESE CASTLE—THE JAPANESE FEUDAL SYSTEM—EARTHQUAKES, FIRES—SENDAI BLACK WOOD.

THE 16th of August saw us at Sendai, where we had business, and where we should have stopped. I was determined, however, to be at Shirakawa on the 18th of August, so as to see all the preparations made by the Americans for the observation of the total eclipse. So I decided that we should travel to this place and come back again to Sendai for our work. I have already sent to England a note on the arrangements made for the eclipse. Had we stayed at Sendai we should have seen it fairly well. We would not, however, have seen the arrangements made for observing it, and, moreover, would not have seen the beautiful country surrounding Shirakawa, so that I by no means regret the extra distance travelled, or the time taken.

The country around Shirakawa is, as I have said, beautiful. It is of hill and dale, valley and rice field. Various of the party, myself included, made several photographs of bits of it, but I don't think that any of them convey a good idea of the nature of the scenery. To me the most interesting place was the castle, which had been selected as the observatory by the Americans, and from which the views just mentioned were taken.

It is a thing difficult to appreciate of this now eminently constitutional and peaceful land, that only twenty years ago it was regulated by a feudal system as complete as that which existed in England in the middle ages; that only twenty years ago there were feudal lords, or daimio, who had their crowds of retainers, fighting men, called Samuri, a set of awash-bucklers, who went about armed with two swords each, who were scarcely amenable to any law, were continually quarrelling and brawling and chopping off each other's heads in a gay and festive sort of manner, not to mention their habit of performing hara-kiri, or of committing suicide by the very nasty method of disembowelling themselves with a knife, very often for no very palpable reason other than, perhaps, "to encourage the others." Of the castle of Shirakawa, it is also almost as difficult to believe that it was only twenty years ago a stronghold of one of these same daimio, and was in actual service. So quickly does the exuberant vegetation of Japan spread and cover every spot left open to it, that the walls of this castle are now clothed in such a profusion of trees, bushes, plants, underwood, creepers, and moss, that they look as if centuries must have passed over them since they were in active service, and must have been kept clear of all vegetation except, perhaps, the large trees.

A Japanese feudal castle is a very different affair from an English castle of the middle ages. The tall, square castle and keep, with which we are familiar in a ruinous condition at home, would have been impossible in Japan, on account of the earthquakes, if nothing else. The so-called Japanese castle would be better understood if it were described as a fort or fortified hill. So far as I have seen, a piece of elevated ground is always chosen for the castle, and this is fortified by heavy embankments faced with stone, and moats constructed in a complicated manner around it.

It is rather less than twenty years since the revolution took place which resulted in the complete and sudden overthrow of the feudal system. Before that time there had been a double rule in Japan, the power being divided in a way too complicated for most foreigners to understand, much less to describe, between the Mikado and the Shogun. The former espoused the popular (or anti-feudal) cause; the latter adhered to the old system. The daimio took different sides, according to the opinions or sentiments they held. Shirakawa was the scene of much fighting. The castle was, at first, in the hands of a daimio who favoured the Mikado, but it was attacked and taken by the Shogun's soldiers. It was, however, retaken within a week by the Mikado, who was finally victorious everywhere.

The evening of the day after the lamentable 19th we made our way from Shirakawa as far as we could by rail on our way back to Sendai; but this still left us nearly ninety miles to do in jinrikisha. By getting up before daylight, however, and by having frequent changes of two men, we managed to do the distance within the day. Dr. Goto had left us at Shirakawa, so that I had only Nagasakisan with me now.

Of the town of Sendai two things particularly remain in my mind. One is a street corner where there are several houses exhibiting the more florid style of ancient Japanese architecture. These houses are, I was assured, over 300 years old. This, it must be understood, is a very rare thing in Japan, the prevalence of earthquakes and of fires, combined with the fact that the flimsy wooden houses that the Japanese build are naturally not very permanent structures, reduce the average life of a house in this country to something comparatively very short.

A word on the earthquakes. There are, in Japan, something approaching 1000 earthquakes in each year. The vast majority of these, however, are quite local, and are so feeble as to be observable only by delicate instruments. Perhaps about once a month there is in any one place in Japan an earthquake distinctly perceptible to those who happen to be awake. I have perceived only one as yet, and that was at Sendai. Shortly after I had gone to bed it came. There was a shock—not violent, but much sharper, more like a blow than I had imagined an earthquake to be—which made the joists of the house creak loudly. Then for about thirty or forty seconds there was a perceptible trembling.

Of course such earthquakes as this do no harm to wooden houses; they slowly disintegrate brick and stone houses, unless certain precautions are taken in building. But since there has been any record of such things in Japan, there have been an average of three or four terrible earthquakes in each century. These have levelled even wooden Japanese houses. The ground is said at the last of these to have opened and swallowed up thousands of people. The loss of life in Tokio alone is said to have been, on the occasion of the last of these, some 20,000 souls.

Naturally, with wooden houses having charcoal fires in them, such an earthquake is generally followed by a conflagration; but leaving the occasions of great earthquakes out of the question, there are continual fires in all towns in Japan. In fact, if one considers the tinder-like nature of the houses, and the way in which they are heated and lighted (with mineral oil lamps), and that the means of fire extinction are of the very crudest, the astonishing thing is that there are not more fires than there are.

It will now be understood how rare a thing it is to see a really old house in a Japanese town.

The second thing that I remember Sendai for is a very beautiful black woodware. The wood is, I understand, fished up from underneath the river which passes through the town. It is quite black, and very beautiful trays, &c., are fashioned out of it. The most extraordinary thing about it is its weight. Dr. G. Cargill Knott has taken the specific gravity of one of the carved trays that I bought, and finds that it is very nearly 1.3.

W. K. BURTON.

THE YORK EXHIBITION.

THE photographic department in this International and Industrial Exhibition can scarcely be said to be a success, the exhibits being comparatively few. Various causes have been assigned for this, one being the duration of the Exhibition, the exhibitors being kept out of their pictures from May 5 to its close in October. Another, which probably acted more powerfully, was the charges for space, which, according to Rule 9, are as follows:—

"The charges in Division A will be 1s. 6d. per square foot, with a minimum charge of 3s., any fraction of a foot to be charged as a foot. In Division B the entrance fee will be 10s. for each picture. In Division C the charge for space will be 1s. 6d. per foot, with a minimum charge of 5s. In Division D the charge for floor space will be 3s. per square foot, the minimum charge being 5l."

In explanation, Division A represents—

The Amateur Competition, open to all; the negative must have been exposed, developed, and printed by a *bona fide* amateur.

Division B, the Professional "Champion" Competition, open to all, but limited to one photograph from each competitor, which has not taken a champion prize elsewhere.

Division C, open to all professionals, the number of photographs not being limited.

Division D, Photographic Apparatus, Medals, and Diplomas to be awarded for the best specimen and collection of apparatus, or for any appliance of special merit.

Medals in gold, silver, and bronze, together with certificates, were placed at the disposal of the judges—Messrs. Henry Moore, A.R.A., H. P. Robinson, J. Traill Taylor, Charles W. Hastings, and W. Monkhouse, who had power to give or withhold them wherever they saw fit.

This power they exercised with the following results:—

DIVISION A.—AMATEURS ONLY.

Class 1 (*Champion Gold Medal for the Best Photograph, &c.*).—Prize withheld.

Class 2 (*Architecture*).—Silver medal, F. P. Cembrano, jun.; bronze medal, M. B. Copland.

Class 3 (*Landscape or Seascape*).—Silver medal, B. G. Wilkinson, jun.; bronze medal, Rev. F. Stow.

Class 4 (*Portraiture*).—Silver medal, withheld; bronze medal, Miss Clarisse Miles.

Class 5 (*Instantaneous*).—No awards.

Class 6 (*Genre or Figure Studies*).—No awards.

In this division all the medals are given by the proprietors of the *Amateur Photographer*.

DIVISION B.—PROFESSIONALS ONLY.

Class 7 (*Champion Gold Medal for the Best Photograph, &c.*).—Prize withheld.

DIVISION C.—PROFESSIONALS ONLY.

Class 8 (*Architecture*).—Silver medal, Lyd Sawyer; bronze medal, withheld.

Class 9 (*Landscapes or Seascapes*).—No awards.

Class 10 (*Portraiture*).—Silver medal, W. W. Winter; bronze medal, W. P. Glaisby.

Class 11 (*Instantaneous*).—Silver medal, Henry Symonds; bronze medal, withheld.

Class 12 (*Genre, &c.*).—Silver medal, R. W. Robinson; bronze medal, withheld.

DIVISION D.—PHOTOGRAPHIC APPARATUS.

No awards.

There being so few photographs in the Exhibition which have not been seen in many others, description or critical comment is not here considered necessary.

But as if to make amends for the paucity of the photographs, there is a large and truly admirable collection of paintings in oils and water colours by masters both ancient and modern. There is also a fine collection of statuary. In the galleries devoted to these works of art one may spend many hours pleasantly, and with profit. But apart from these, the general Exhibition also is of a high class. Although it would be quite out of place to contrast it with the recent exhibitions in Manchester, Glasgow, or Newcastle, cities famous for their manufacturing industries, yet is this one in York not to be lightly esteemed. We failed, however, to observe any stalls possessing features of special interest to the photographer, except that of a local optician, Mr. J. M. B. Smith, who shows a nice selection of lenses, cameras, and numerous other photographic appliances by makers of high reputation.

Mr. Joseph Davis, the General Manager, is a capital caterer, and provides ample stores of instruction and amusement for the visitors, especially for the large numbers who frequent the Exhibition and grounds during the evenings.

JACK AND I IN NORWAY.

VIII.—FALEIDE, UTVIKEN, RED, AND HAFSTAD.

In the valley of Grodaas we got some very interesting and characteristic studies. There were little wooden saw mills perched on the rocks at the entrance to the glens, built at points where the falling water from the glen could be easily led into them; some of these with their surroundings made very picturesque and typical pictures of the country. These little mills, used for sawing wood, are scattered all over; we found them in every nook and corner, in the most secluded spots where water was to be procured we came upon them plying away. As all the houses are made of wood, the demand for it must be great, and hence this industry must be one of the largest in the country, wood here taking the same place as stone and brick with us. Wherever there is a plantation to be found and a stream near by, there is sure to be heard the grinding of the mill and the whirring of the saw.

After we finished here we drove on to Faleide on the Nord Fjord. The drive from Grodaas to Faleide is very pleasant, and especially from Kjos, the station between the two places. Onward from this point it is very thickly wooded, and romantic-looking lakes could be seen glinting through the trees as we journeyed on.

Faleide is a favourite resort, and many English people stay here for a month or two at a stretch in the summer-time. It is a very picturesque place of itself, besides being a good centre, so many places of interest lying within a few miles of it on all sides. The hotel at Faleide stands like the one at Grodaas, overlooking the fjord, in the most enviable of positions for prospecting. This hotel looked a very peculiar habitation when we got our first look at it; the wooden front seemed as if it were stuck upon a rock about two storeys high; the entrance to the house was by a doorway cut in this rock, and the stairs and apartments in the lower part were roughly hewn out of the solid rock, the walls left with protruding pieces and chisel marks. These are the working rooms, which must be deliciously cool in summer. One stair up brought us to the wooden edifice which was the hotel proper and the visitors' rooms. After exhausting Faleide we had to continue our journey in a small rowing boat across the fjord to Utviken, a distance of seven miles. We had two most antiquated specimens of boatmen to row us over. If any one had told me that they had come out of the ark, I would have been inclined to believe it. We started; the wind was dead against us, and the water came lashing all over the side of the boat with every thud of the waves, soaking both ourselves and

our traps, whilst the ancients shook their wise old heads and smiled, and talked away in their native tongue (they had no English) through their gums (they had no teeth), and they toiled and sweated and drank any quantity of water out of the lake, which they drew up with a bailing *cog*—a wooden vessel shaped like a shoe. Jack made up his mind to have a picture of these two old men of the sea, and we tried all we knew to get them to understand. They seemed to know what we wanted, but they would not have it. When we reached the other side we gave them tips to try to induce them. They kept the money, but they would not stand. After disappearing for a little they returned, each with a large flour scone under his arm. I am sure they would be twelve inches in diameter. This was their food, and water was their drink. As we stood waiting on our stolecarrie we saw these two old men away out on the troubled waters toiling homewards, fighting with all their might against the wind that came sweeping down through the mountain gorges. And what, think you, was the remuneration that those poor souls received for all this toil? Only 1s. 1½d. per man, or a sum total of 2s. 3d. for the two! This for toiling through rough water for fourteen miles, when you count the journey home again; all that you give above and beyond this 2s. 3d. you give of your own free will, for that sum is all the law allows. No wonder, then, they thought it a waste of time to be photographed.

The first part of the road from Utviken to Red was very rough indeed. The farmers that were supposed to keep the roads in order must have been away from home in these parts, for, to begin with, it was no better than an unfinished pass up the mountain side, with many stumbling blocks, in the form of stone, roots, bits of rock, and other *débris*, strewn all over the way, but the road improves much as we proceed. On this journey we had an irritatingly cautious driver—the first time we had met that virtue in all our journeyings; he got down and looked at the horse's feet, he next got down and inspected the harness, he could not allow the pony to run up hill for fear of breaking his wind, he would not let him run down hill in case he would fall and hurt his legs. And this game continued for about seven miles, when Jack got so exasperated that he let the old fool have a round of the guns in English, which our noble conductor received in quite good part and with an imbecile smile. "Oh, this will never do," exclaimed Jack, when *Caution* got down for about the twentieth time to inspect something; and springing from the stolecarrie on to the road, he said he was going to walk, as he considered it better than staying with that old ass fooling around—life was too short for that sort of thing—and away he went. I sat still, as I was not in any hurry, and although we were going along slowly, I felt comfortable enough, for we were getting down to the lower level, where travelling was always easier.

Jack stepped out and was hidden from our view in no time, and the old man, instead of sitting on the luggage behind, came on front into Jack's seat to enjoy the comfort when he had the chance. We bowed along very pleasantly, for when we got down to the flat, which we did shortly, the nervous terror about his beast left the old man, and he allowed the pony to exercise its own sweet will, which was to go. We came up with Jack after he had walked about six miles; he stood in the middle of the road awaiting our approach, and eying the old man most wrathfully. "Where the mischief is the portmanteau?" he exclaimed, pointing to the back of the conveyance—where it was not. You see, the old man had undone it to make it more easy to sit on when he was driving there, and he had forgot to fasten it when he came into Jack's seat, and so our portmanteau—for we had only one between us—with every bit of clothing, day and night, belonging to us had dropped off on the road without our observing it. The thing might be six miles back, and it was close on twelve o'clock at night—here was a fix! and I can tell you that it did not improve Jack's temper.

"You go right back and find that portmanteau, and bring it on to Red, though it should be four o'clock in the morning, or I'll know the reason why. I will make it pretty hot for you! On you go!" he said, as the old man looked defiance, and said he would wait till the next day. "Nothing of the kind," said Jack; "you go on now, and we will walk to the hotel at Red and wait for you." The old man made another little effort at resistance, but Jack was too many for him, and slowly and sadly he turned the vehicle round and moved along the road we had just come, looking for our missing wardrobe. We had a two-mile walk to Red, and when we reached the hotel explained how matters stood, and they had a hearty laugh at us, but assuring us at the same time that the portmanteau would turn up all right; so we sat down to supper slightly consoled, and before we had finished, our charioteer appeared with all our goods and chattels; he had picked up the portmanteau on the road some three miles back.

I was glad he came so soon, as we had arranged to try an exposure at midnight, and the style of this place favoured the attempt, the only thing that seemed against the success of the experiment was the number of people that were moving about. There had been a shooting match in the village of Red that day, and the young fellows had come in from all quarters to it; and it was wonderful to see how jolly they get on the light beer they drink, for they can't get spirits to buy; they were going about as lively as if it were the forenoon instead of midnight. When we had the camera fixed, and making the exposure, I was timing it with my watch in my hand, for we were giving it six minutes; in the midst of this wait a cheery-looking native came alongside of me and also pulled out his watch—it was scarcely so large as a cart wheel; he stood there smiling

when I remarked to him in English that my watch was far better than his, for I could double it up, in fact, that it was as pliable as indiarubber, and then by the well-known trick I bent it backward and forward and seemed to double it up. He stood aghast. The exposure was concluded, and my friend still stood and gazed, when I passed several coins into his pockets—which afterwards he did not find there. To watch that man from the hotel window for the next half hour was as good as a pantomime; small groups of people were gathered round him, and he was explaining the watch trick and trying to pass the money, with many gesticulations and considerable energy; he was still at it when we went to bed. Red, as a village, was much better situated for photographic work than many of the other places we had visited. The lake on the edge of which it stood was all surrounded by hills, that came so close that the village seemed shut in. We had the advantage of getting down quite close to the water's edge, that helped out the composition of pictures considerably; so many of the other villages were so situated that views of them had to be taken flat-on if we wished to get representations of them at all, so that our exposures here were highly satisfactory.

We left Red in a rowing boat and sailed down the lake some ten miles, and it was as smooth as glass, this water being so sheltered by the hills. One object of interest here is the Rittelen Mountain, which has a large hole right through it. We had not proceeded on our journey more than a mile when we observed the young girl from the hotel rushing along the bank and evidently waving to us, we put back to see what was wrong, wondering what could be up now. Jack had left his pocket handkerchief. That girl must have run a mile at least, and to see her delight on receiving a silver piece, value some 7½d., for her trouble was amusing. If a kingdom had been bestowed upon her she could not have manifested more joy.

We reached Forde, which lies at the other end of the lake, and we took a picture of our boat and boatmen, but the subjects were commonplace compared with the old men who would have none of it. This place Forde is also named Hafstad, their being another Forde a few miles further on, and two places of one name so near is apt to cause confusion.

We got a stolecarrie and proceeded on our way along a good road amongst the hills, having a considerable quantity of the switchback element about it—up and down. The cliffs here are very rugged and overhanging, and the comparatively flat parts are all strewn with immense rocks and stones that giants in mythological times might have been delighted to play with. By-and-by we come upon more cultivated ground as we leave the heights and descend into the valley, where we have a beautiful view of a charming lake in the distance, which, in course of time, we come close to the edge of. For fourteen miles we drove along the side of this water—Jölster Lake—with charming views at every turn, we, meanwhile, stopping and taking whatever struck our fancy, and in the evening drove into Nedre Vasenden, which means the lower end of the water.

MARK OUTE.

A DAY'S OUTING WITH A CAMERA IN KENT.

It was a bright morning in the present leafy month of July, and the country was bathed in all the glories of its splendour, when, having accepted the invitation of a gentleman—an enthusiast in his art—we joined him in a day's photographic expedition throughout that portion of the country-side which could be compassed and exhausted in the day before us. We may premise that within the past few years the art-science of photography has made rapid strides. In the early days of the art, photographers had not the command of the delicately constructed and much-perfected apparatus which now form the appliances of successful photography. Then cameras and lenses were of comparatively rude construction, whereas now science and constructive skill have combined to place photography in the foremost rank of remarkable human inventions. We may say for the "nonce" that our *compagnon de voyage* was Mr. C. Vernon, of Tonbridge-road, Maidstone, a gentleman who has signalised himself as a master of the art of which he is so devoted a teacher and disciple. The comfortable trap which took us on our road was packed with tripods, together with rosewood cases containing the mysterious "Open, sesame!" all ready for sudden and immediate utilisation by our friend the operator.

A delightful drive through a country which was literally fresh in living green, and the air of which was suffused with the sweet odour of the honeysuckle and the hawthorn, brought us to the grim old, but picturesque, ruins of Allington Castle, once a noble structure, and of which history records stirring events. Choosing the most advantageous positions, several capital plates of the exterior and interior of the massive ruins were secured. The position of the castle, standing high above the back of the meandering Medway, the beauties of its ground and the rich foliage of the finely wooded country around, all combined to form a scene the very loveliness of which made us loth to "move on." Pushing on through a country which may be truly described as paradisaic in its beauties, we arrived at the noble mansion of Preston Hall, Aylesford, the seat of H. A. Brassey, Esq. The park in which the mansion stands displays its sylvan beauties with bounteous lavishness. The deer, posing with natural grace, were cropping the fresh herbage; away to the right was the picturesque village, its sacred fane standing high above it; and far away in the blue distance were the famed Kentish hills, "shimmering in the sheen" of the July sun. Plates of the front and the back of the

mansion were well realised, the Dallmeyer lenses giving powerful definition, and the light was admirably suited for the purpose.

After a few moments of enjoyable lingering in the park we visited the old Friars at Aylesford, the seat of the Dowager Lady Aylesford, but now occupied by Captain Carter. This grand old pile, the first foundation of Carmelite Friars in England, stands amidst an embowment of foliage overlooking the historic Medway, and furnishes the materials for a sketch which should delight the heart of the painter. Here Mr. Vernon, our courteous guide, exposed several plates, obtaining, as he gleefully informed us, a series of strikingly beautiful views of the venerated structure. Our trap was again requisitioned, and skirting the rural village of Ditton, and passing through little bustling Larkfield, with its prosperous-looking shops and residences, we came to the rhythmically sounding waterfall which forms the principal feature in the Old Swan-street of West, or as the denizens love to term it, Town Malling. The waterfall is the depository result of a stream which rises above the Abbey grounds and disposes itself in this more than picturesque fashion.

The Abbey was in the good old times a Benedictine nunnery, and right merrily, looking at the ruins of the refectory and its collateral surroundings, most the nuns have fared. The Norman tower and portions of the Conventual Church are in a good state of preservation. Passing through the arched gateway we looked in at the chapel on the left, a pretty apartment in itself, but which the Vandalistic hand of so-called restoration has succeeded, as far as the surroundings of the Abbey are concerned, in making to look incongruous. In this pleasant retreat we spent fully two hours, during which a number of realistic negatives of the prominent features of the Abbey and its beautiful surroundings were taken by Mr. Vernon, who, inspired by the love of his art, warmed enthusiastically to his work, and seemed in smiling guise, as he secured each well-defined view, to exclaim in the old classic language, "Eureka! Eureka!"

Journeying from these interesting ruins, we drove to the massive and well-preserved Norman tower known as that of St. Leonard's. The hop gardens surrounding the structure prevented our ardent photographer from snatching a view on the ground, but, with a power of resource which reflected credit upon him, he chose a quiet corner in a neighbouring garden, from whence he secured a splendid negative of the hoary remains of the old and renowned Norman conquest of England. A drive along a capitally made road brought us to Mereworth Castle, a large and handsome mansion standing in a park, the ornamental water of which was conspicuous for its beauty. The noble owner, Viscount Falmouth, it occurred to us, had been photographed by Mr. Vernon for a portrait in the *Graphic*, and on reminding our travelling *compère* of the fact, he modestly replied that it was a soft impeachment to which he must plead guilty. Several views of the Castle, adding to those which at different times had been taken by our versatile photographer, were secured, and seeking shelter and refreshment from the heat of the day, we repaired to the comfortable hostelry of a neighbouring friend, who treated us with cheerful and hearty hospitality.

On the road home we tarried for a time at Wateringbury, and this was utilised for taking negatives of the interior and exterior of the ancient parish church, and for obtaining plates of the several members of the famous pedigree stock of Mr. Herbert Leney. The day's labours were, to our mind, sufficient in themselves; but notwithstanding the continued exposure of his lenses, Mr. Vernon, with a love of his art which did him credit, could not refrain from taking, as meal-times were passed, several groups of artistically posed kine, to whom the lazy enjoyment of chewing the cud lent enchantment to a pastoral picture. Wondering at the rapidity with which these negatives were taken, Mr. Vernon informed us that he used the most rapid plates, instantaneous shutter, and the whole of his apparatus was of the most modern description; without these his efforts would have been powerless.

We arrived home after a day of unalloyed delight, bearing with us the sweetest memories of an art which can bless, immortalise, and bring one in direct contact with the relics of the past, and the beauties of ever-gladdening and inspiring nature.

It. W. H.

A NOTE FROM NORTHUMBERLAND.

A STROLL round Newcastle and district, with special reference to the photographic studios and displays, is interesting as showing the immense disparity in quality, execution, and artistic excellence between the work of some four or five artists and the remainder of the brethren. Particularly good is the display of platinotypes by Mr. Bacon, of Northumberland-street, Newcastle. Mr. Bacon's window, when seen by the writer, contained no specimen whatever of silver printing, and the general effect was very fine and pleasing. Mr. Lyddell Sawyer, opposite, is well in front with his silver work, but I cannot help thinking that Mr. Sawyer's best work is kept "out of the show cases." Mr. Brewis, a comparatively new starter, is rather handicapped by his situation, but makes a good show, well worth notice. Mr. Anty, at Tynemouth, "holds the field," his show room, decorated principally with enlargements—carbon, platinotype, and bromide—of some of his well-known sea and landscapes, portraits, &c., makes a very impressive display; while Mr. Parry, on the other side of the water, with his splendid photographs of shipping, engines, models, workshops, &c., instantaneous and otherwise, including

portraits, shows a general excellence sufficient to turn the ordinary photographer "green with envy."

Mr. J. P. Gibson's (of Hexham) reputation is now established. One could spend hours in looking through this gentleman's albums of lovely "bits," "studies," and other representations of the beautiful scenery to be found near and around this historic town. Mr. Gibson's large work does not impress one so favourably as his smaller landscapes.

Mr. Hodges, of Hexham, well known for his splendid illustrated work on *Hexham Abbey* and other publications, is achieving a name also for his architectural photographs, principally in platinotype, of antiquarian interest.

The recent visit of the "Shah" gave the local body of amateurs and professionals an opportunity of trying their "shutters," which, judging by the number of cameras to be seen on the line of route, seemed very generally taken advantage of. The net result, as shown by one solitary specimen, is disappointing, and forms a fit subject for reflection and conjecture as to what proportion the number of successful attempts at "detective" photography bears to the number of plates exposed and the cost of apparatus used.

Foreign Notes and News.

THE amateurs of Havre and the lower Seine district have definitely arranged to establish a photographic club, to be entitled "Le Photo-Club, Havrius." More than sixty local photographers have been enrolled as members, and everything seems to promise well for the future of the new Society, the more especially as the composition of the Administrative Committee, numbering as it does among its members MM. Rougé (President), Perrichot (Vice-President), Albert Goupil and Professor Soret, gives a more than sufficient guarantee that the management of the Club will be conducted with energy and success. The Society, it appears, intends to make a speciality of marine landscapes, and in conjunction with the Photo-Club of Paris and several other societies, is making preparations for a sea excursion on a very large scale. We wish every success to the undertaking.

DR. PROFESSOR ENER, of Vienna, has recently been elected an honorary member of the *Dansk Fotografisk Forening* (Danish Photographic Society) in Copenhagen.

PROFESSOR DR. STOLZE writes, that which is already known to some of our readers, viz., that there is no necessity to add bromide of potash to oxalate developer, as the bromide produces a grey tone; he prefers altering the period of exposure. For avoiding yellow colouration in the whites, he points out that if one adds water to a normal oxalate developer, it rapidly becomes turbid through precipitation of ferrous oxalate; precipitation is also produced when the print is placed in water for washing, even when the water is acidulated. The remedy is to be found in the employment of a weak developer—for example, one part of iron to five of oxalate—the print may also be placed in a fresh solution of oxalate. If by any chance the image has acquired a greyish tint, the print may be improved by leaving it in the fixing bath for half an hour, which acts, however, more energetically if it contains alum. Another method of toning gelatine-chloride paper, according to Dr. Stolze, is to treat with a bath composed as follows: Dissolve 35 parts of hypos, 9 parts of common salt, 4 parts of alum, and 2 parts of sulpho-cyanide of potash in 150-250 parts of water, and before using add a few cubic centimetres of a two per cent. solution of chloride of gold.

THE *Pharmaceutische Post* gives the following receipt for a good solution of gum:—

Crystallised sulphate of alumina	2 grammes.
Water.....	20 c.c.

To this add 250 grammes of a strong solution of gum, made in the proportion of two grammes of gum to five grammes of cold water.

HERR JOSEPH ARMBRUSTER, of Freiburg, promises to exhibit, at the forthcoming meeting of various photographic societies at Weimar, an apparatus, or perhaps rather the rudiments of an apparatus, which he has constructed to obviate the shaking of the camera so frequently caused by the liberation of instantaneous shutter arrangements. His apparatus, in its present condition, appears to be composed mainly of cardboard, and to be held in position in front of the objective by hand. Herr Armbruster admits that if his apparatus were to be constructed by some one accustomed to the manufacture of instantaneous arrangements, more satisfactory results would probably be obtained. In this opinion we venture without prejudice to agree with him, and to suggest that Herr Armbruster is to be even more congratulated for having drawn attention to an existing evil than for his success in devising a means of obviating it.

HERR OTTOMAR ANSCHÜTZ, of instantaneous reputation, has furnished the Sport and Fishery Exhibition, now being held at Cassel, with an interesting exhibit. A dark chamber has been fitted up in one of the walls, in which is a square opening. This opening is successively filled, at such small intervals of time as to render the impressions produced practically continuous by a changing series of instantaneous photographs. The photographs thus exhibited comprise subjects from the riding school, soldiers at the march past, gymnasts on the horizontal bar, &c. Every detail of movement is represented by a separate image, which occupies the opening before the eye has had time to perceive the removal of its predecessor. The result is that the observer sees successively pass before his eyes the rising and falling of the horseman in the saddle, the elastic play of the horse's limbs, the movement of the hoofs, the scattering of the sand, the constant alteration of light and shade produced by the various muscular movements—in short, a changing picture, as though one were gazing through a window upon a horseman in full gallop below. The value of instantaneous pictures, when exhibited in this manner as a means of throwing light upon the real movements of both men and animals, can hardly be exaggerated, and can scarcely fail to prove of high interest both to the artist and the physiologist. Herr Anschütz is a worthy follower in the pathway first opened by Mr. Muybridge.

PATENT COMPLETED.

AN IMPROVED BOX FOR PHOTOGRAPHIC PLATES.

No. 13,082. FREDERIC BARRETT, 165, Queen Victoria-street, London.—July 13, 1889.

THIS invention relates to the manufacture of an improved box for containing photographic dry plates; the main object of the improvements being to provide a box which, while being light, shall be strong and light-proof.

In manufacturing my improved box I form the ends thereof of wood, provided with a number of vertical grooves placed at a suitable distance apart, and adapted to receive the edges of the plates, the outer grooves serving to receive the sides of the box, also made of wood and adapted to be slid in or out. The permanent sides of the box, as well as the bottom thereof, are made of cardboard or the like. The space between the removable wooden sides and the permanent cardboard sides of the box serves as a cushion against the effect of blows or pressure during transit or otherwise.

In practice I find it advantageous to provide the upper edges of the box with a flap of non-actinic paper, to be folded over the edges of the plates before the lid is placed over the box, as a further protection against the entrance of light, particularly after the box has been once opened.

The lid of the box is made of cardboard, and is adapted to fit over the top of the box as usual. The bottom of the box, as well as the inside of the lid, is advantageously strengthened by means of a thin piece of wood or of corrugated paper packing.

By this improved construction of box I obtain absolute security against the entry of light, combined with rigidity, at the same time that the plates can be placed in and removed from the box with facility, and efficient protection against injury is afforded to the plates during transit and otherwise.

„ 15.....	London and Provincial	Masons Hall Tavern, Basinghall-st.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AUGUST 1.—Mr. W. M. Ashman in the chair.

Mr. F. A. BRIDGE called attention to some much blistered prints on argentic bromide paper. Another print made on paper of a previous batch and developed and fixed with these was without blisters, showing that the fault lay in the particular sample of paper. Alum had been used before fixing, but

without avail. The only remedy that he had found to be effective was to immerse the print for some time—three-quarters of an hour—in methylated spirit.

The CHAIRMAN said that in very bad cases of frilling plates he had known a whole night's soaking in methylated alcohol to get them down. Chrome alum added to emulsion tended to prevent frilling, but if more than about one-eighth of a grain to the ounce of emulsion was added it was apt to coagulate the gelatine. He would like to know whether acetic acid had been tried for relieving emulsion that had been thus coagulated.

With respect to the Eikonogen developer, Mr. A. COWAN said that he had used a solution for developing several plates in succession and then left it uncovered in a dish for twenty-four hours, and found that it would still develop. For some plates he considered that the addition of a little bromide was advantageous.

Mr. F. P. CEMBRANO remarked upon different characteristics of prints by platinum and silver from certain classes of negatives.

The CHAIRMAN said that a well-known London photographer made it a practice to ascertain, if possible, before taking the negative whether silver or platinum prints were likely to be required; if the latter, he made the negative much denser and took care to keep the shadows perfectly clear.

Mr. CEMBRANO then opened the subject of the evening—*Camera Stands*—and said that in the *Photographic Review* the desiderata for camera stands for field use had been pointed out. One stand which he showed met most of the specified requirements, and in one particular—lightness—rather went beyond them. The particular stand he exhibited was less than three pounds in weight, would extend to five feet, and pack at twenty-two inches in length, and would go into a portmanteau. It was very solid though so light, and the legs were both folding and sliding. He considered the sliding leg to be very important, as it was not only so much easier to work on uneven ground, but by extending one leg and shortening the other two it became possible to plant the camera close alongside a wall or other object. Camera stands of other constructions were also shown; one of these, the Brattice stand, was remarkably rigid and firm. The head of the stand, he thought, was best made as a turntable, forming part of the camera.

Mr. COWAN said that it was very useful at times to be able to vary the length of one or more legs of the stand, an arrangement which the sliding form made quite easy. In one case that he remembered, when photographing from the side of a steep bank, he had one leg made expressly several feet longer than the others, and so was enabled to work the camera at the only place suitable for the particular subject.

AMATEUR PHOTOGRAPHIC ASSOCIATION.

A COUNCIL meeting of this Association was held on July 20 at 53, Pall Mall, the Right Hon. the Lord de Ros in the chair.

The minutes of the last meeting having been read and confirmed, the following members were elected:—Monsieur le Viscomte de Condeixa, the Hon. Maude Lawrence, Rev. George Perram, Messrs. H. C. Lawton, H. O. Hutchinson, and Fred. Wrigley.

The Secretary then laid before the Council the pictures for the current year, which had been arranged and classified by Mr. Glaisher (Vice-President). There were in the first class 144 pictures, being, with one exception, the largest number ever contributed in the first class.

The Council, after examining every picture, and confirming in almost every case Mr. Glaisher's marks, awarded the following prizes:—To F. S. Schwabe, the first prize, for Nos. 4, 82, 107, and 108, a large silver goblet. Mrs. Hobson, the second prize, for Nos. 74, 84, and 91, a silver goblet. R. Leventhorpe, for Nos. 184, 185, 187, and 188, a silver goblet. W. Muller, for Nos. 254, 256, and 257A, a picture in frame. R. O. Milne, for a series of large views, a medal. W. S. Hobson, for Nos. 354 and 356, a medal. W. Gaddum, for Nos. 15, 18, 37, and 70, a picture in frame. F. Griffith, for Nos. 7, 11, 15, and 17, a handsomely bound album. L. Ashburner, for a very different Indian interior, a medal. W. Dumerque, for Nos. 14 and 28, a small silver goblet. The Right Hon. the Lord de Ros, for Nos. 39 and B, a medal. Surveyor-General Foster, for No. 1, a handsomely bound album. M. de Déchy, for No. 22, a medal. R. Murray, for Nos. 241 and 242, a medal. P. Gunyon, for Nos. 634 and 653, a medal. Mrs. Benson, for artistic portraiture, a medal. F. G. Smart, for Nos. 6 and 10, a portrait album.

NORTH MIDDLESEX PHOTOGRAPHIC CLUB.

JULY 22.—Mr. J. L. Treadway in the chair.

Six gentlemen nominated for membership at the last meeting were unanimously elected.

Samples of Oldham's dry powder developer sent to the Secretary were distributed.

Mr. STEWART read a paper on *Autotype Printing*, giving a history of the process from the time when the effects of the bichromates upon gelatinous substances were first noticed until the present time. He then proceeded to illustrate the practical details of the subject.

The Autotype Company kindly lent samples of finished prints, &c.

Mr. WALKER raised an objection to the process from the effects of the bichromates in causing a skin disease, which he said he had been informed most of the Autotype Company's employes suffered from, and stated that he himself had been prevented from using it from that cause, although he much admired the results obtained by it.

Mr. STEWART said that, although he had worked the process extensively, he had never noticed any unpleasant effects to follow. He would also recommend those members who might intend working the process to buy the tissue ready sensitised, as in sensitising it at home there was a difficulty in drying it sufficiently to get good results, as if it took too long in drying it became insoluble without being exposed to light.

It was decided that there should be an outing on Bank Holiday to Welwyn, train leaving Finsbury-park at a quarter to eleven. The Great Northern Railway has consented to issue reduced fares; therefore all members and friends intending to be present are requested to communicate the same to

Mr. S. Quincey, Blenheim-house, Harringay-road, West-green, and meet at Finsbury-park Station at twenty-five minutes to eleven to facilitate procuring the necessary tickets. Visitors invited to attend.

SHEFFIELD CAMERA CLUB.

AUGUST 2.—The President (Dr. T. H. Morton) in the chair.

Mr. H. J. HARDY (Hon. Secretary) exhibited some excellent instantaneous studies taken by Mr. J. O. Arnold. The prints had been toned with chloride of gold and soda carbonate, which he thought was superior to soda bicarbonate, as used generally.

Mr. HARVEY RAWSON introduced the topic of the evening—*Clouds*—and said that early in his photographic experience he saw the necessity of having clouds in landscape pictures; there could be no comparison between views with clouds and those without. When they were absent he printed them in from a special glass cloud negative, and preferred a thin image, but with contrast. Having shaded the foreground, clouds were soon printed in the plain sky. Masking required skill to avoid showing evidence of double printing. Clouds were not easy developing, and he thought that the use of yellow-tinted glass placed behind the lens would obviate or reduce, during exposure, their intense brilliancy. A pinhole camera might prove effective. A number of cloud negatives were shown as illustrations, also capital prints of scenes in Derbyshire and stereoscopic views.

The President read a short paper as follows:—

The subject—*Clouds*—is one of considerable interest to photographers, and hardly has received the attention which it deserves; at least, I have not met with much written concerning them. It is the wish and delight of the landscape photographer to obtain a fine cloud effect in his picture by one and the same exposure, but how often does this occur? The reason, if not fully understood, should be ascertained. When you have a deep blue cloudless sky with brilliant sunshine, or a light blue with faint haziness or thin cirrhus cloud, I need scarcely say the resulting negative is dense and valueless as regards the sky. The clouds have to be printed in or a certain tone given the paper, according to the composition; but even if fine, bright cumulus clouds are present when exposure is made they most frequently become obliterated during development before the foliage, rocks, or other dark objects have reached a proper printing density. If we could safely stop development of the sky at an early stage the clouds would be evident in many cases. This fact being recognised points to unequal lighting as a cause of clouds being absent from the negative. The foreground, &c., is under and the sky over exposed comparatively, and if one could differentiate the developer, i.e., give more to foreground and less to sky, much would be accomplished, but in this lays the great obstacle. I possess a number of negatives in which clouds are present and print fairly through without any dodging. Some were taken by drop shutter and others with an exposure of as much as six seconds. Now, in reference to my note book and a recollection of the views how they were lighted, I have come to the conclusion that even illumination was in most instances the cause of success. For example, dark round masses of cloud with just a silver margin here and there, and a bright open foreground and few shadows, also some views without direct sunshine but well lighted, are good. I may say that in nearly all the sun was behind or either to right or left of the camera. In seascapes clouds are often caught, as the sea is generally well lighted and is a reflecting surface. The sky being rather more dense in negative than the sea, the latter has to be masked when printing. Cautious development is essential to the securing of cloud and landscape: a solution of pyro, medium strength, with not too much ammonia as a start, and careful watching that the sky does not get too opaque. I find that keeping the developer well on the foreground by tilting the dish upwards, relieving the sky of its action, has a marked good effect. Of course a thin sky can be made by over exposure or a weak developer. In taking cloud negatives specially, a drop-shutter exposure, if light is strong, lens at $f/16$, rapid plate, will answer; a developer rich in pyro—say three grains to the ounce—and one drop of ammon. fort. and one grain of bromide in each two ounces of solution; develop until the cloud contrasts are just overdone, wash and fix. Some photographers have recommended a slow plate and rather long exposure, but this would bring matters almost to the same condition as in the former method. The ever-varying light intensity of clouds, the position of sun, and time of day, will always need discrimination in exposure, but any rules or suggestions that could be made to facilitate securing clouds in our views without combination printing would be hailed with satisfaction.

Mr. G. T. W. NEWSHOLME, M.P.S., observed that he had taken several views recently with short exposure and lens stopped down, and obtained good clouds, but the foreground refused to develop.

Mr. HARDY thought that Dr. Vogel had recommended a tinted glass screen.

Mr. Borbidge and other members joined in the discussion.

Correspondence.

Correspondents should never write on both sides of the paper.

THE STANNOTYPE PROCESS.

To the Editor.

SIR,—In your issue of July 5, p. 437, under the heading *Neglected Processes—Stannotype*, you say that stannotype is "analogous in principle to the Woodbury process, and capable of giving as good results."

It seems strange that you have not observed that stannotype is radically defective (which Woodburytype is not) because it narrows every depression and broadens every elevation by twice the thickness of the tinfoil (or other layer). That is to say, if the tinfoil was one-eighth of an inch in thickness, then every hollow would be narrowed and every elevation broadened by one-quarter of an inch. Should you doubt this,

cut out a card the shape of a W, measure the width of the hollows, then put a layer over the outline and measure again, and note the result.—I am, yours, &c.,

WM. BIRRELL.

[Our correspondent overlooks the fact that the image is raised as well as broadened. In actual practice the stannotype process produces charmingly sharp and fine impressions.—ED.]

PHOTOGRAPHING DISTANT OBJECTS BY A TELESCOPE.

To the Editor.

SIR,—Under the head of "Foreign Notes" (p. 511) you quote from an article by Mons. A. Rossignol on this subject. The writer, however, entirely misapprehends the action of the telescopic eyepiece when he says, "But as the last glass of the eyepiece renders the rays of light almost parallel, nothing prevents the image from being repeated at the focus of the photographic objective," and so on. Now it is a well-known fact that the rays of light which issue from a telescopic eyepiece are not parallel, nor even almost parallel; they are converging parallel rays, a very different matter. How, then, can M. Rossignol focus them by means of an ordinary photographic lens and camera, as he states he does? In wonder he gets what he is pleased to call "a want of sharpness shown by the proofs thus obtained." The fact is he has gone about it in the wrong way. There is no necessity for using the photographic objective at all. He lays most of the blame upon the eyepiece because, he says, "it is deficient in proper curvature and is not achromatic." Both of these reasons are wrong. An ordinary Huyghenian eyepiece when used photographically has the very best curvature for the purpose, as it gives exceedingly flat pictures, and it is well known that it is achromatic when used in combination with a telescopic or microscopic objective.

I have been led to draw attention to this matter from the fact that in a book just issued by Sir Robert S. Ball—*The Story of the Heavens*—there is a diagram of the action of the telescope upon the rays of light passing through it in which the rays after leaving the eyepiece are drawn as parallel, and not converging parallel, as they ought to have been. I should have thought this oversight, for it can be nothing else surely in so eminent a man, would have been corrected in this new edition, but there it stands in my copy. Of course if the rays are simply parallel when they leave the eye-lens, how can the eye ever pick them up? But when they are converging parallel they are brought to a focus, and they all enter the eye at the focal point.

I am not speaking without the book. I have made a number of experiments in photographing distant objects by means of a telescope, and very interesting it is. I should, however, as soon think of placing a telescope in front of a photographic lens and camera and taking a photo micrograph in the same way, which every one knows would be absurd.—I am, yours, &c.

PROCELLA.

Exchange Column.

* No charge is made for inserting Exchanges of Apparatus in this column but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Will exchange double-barrelled breach-loading gun, with cartridge case, &c., complete for half-plate camera and lenses.—Address, CRAIG, 130, Otley-road, Bradford.

Half-plate condensers or enlarging lantern wanted in exchange for whole-plate portrait lens. Difference adjusted.—Address, S. K., 4, Cemetery-road, Weaste, Manchester.

Exchange Lancaster's half-plate Meritair, three double backs (wood), old pattern for good quarter-plate set or detective.—Address, MERITAIR, Rock-cottage, Instow North Devon.

Wanted, a good quarter-plate outfit in exchange for a national mechanical organett with seven popular tunes. In good order.—Address, T. HACKING, 10, Strawberry bank, Blackburn.

Will give in exchange for tricycle half-plate camera, head rest, printing frames, bat and dipper, tripod stand, rolling press, and embossing press.—Address, LEWIS, 12, Blackstock-road, Finsbury-park.

MR. W. F. STANLEY has brought out a changing box for celluloid or other films, the bulk of which, he says, is that of two ordinary double backs. It encloses "A Descriptive Circular," but upon reading it we find it to consist only of printed directions for using the changing box, of which, not having seen it, we are unable to speak as to its merits.

THE DEMON PHOTOGRAPHER ON BOARD SHIP.—The professional photographer nowadays is a ubiquitous animal, but nowhere does he come more to the front than on the "briny wave." Although he photographs every event of the slightest public importance, he has an especial fancy for ships and sailors. He is scarcely in dock before he appears with his camera, and when she goes out of harbour he is seen rushing from point to point, taking her in every possible position. When he comes on board, and has obtained permission to photograph the officers, he sets up his camera, "takes charge," as the nautic saying is, of the whole place, and finishes by insisting on every sitter purchasing two or three copies. This the sitters usually do, being in high good humor at having at last finished the ordeal of being "grouped," and cramped in various uncomfortable positions for the best part of half an hour. As the photographic also disposes of a large number on shore, he certainly "goes to windward" in the transaction.—*Graphic*.

Answers to Correspondents.

•• Communications relating to Advertisements and general business affairs must be addressed to "H. GREENWOOD & Co.," 2, York-street, Covent Garden, London, W.C.

All matters for the text portion of this JOURNAL, including queries for "Answers" and "Exchanges," must be addressed to "THE EDITOR," 2, York-street, Covent Garden, London, W.C. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.

PHOTOGRAPHS REGISTERED:—

W. Draper, York.—Photograph of oil painting representing and entitled "St. Robert of Knaresbro'."

Charles de Joux, London.—Twenty-eight photographs of views in East Africa.

R. Symons, Tenby.—Photograph of St. Catherine's Rock and Fort, entitled "Find the Shah."

W. E. H'OO.—No address given.

CLARKE & CLARKE.—Imperfect fixing.

J. DAVIDSON.—The sulphur will do no harm, it will be simply burnt away in the reducing.

J. BATE.—Formulae for the powder process have appeared in each ALMANAC during the last ten years. To these we refer you.

X. Y. Z.—Wilkinson's treatise, second edition. It is published by England Brothers, 6, St. James's-square, Notting-hill, London.

H. R. H.—*Harmonious Colouring*, published by Newman, Soho-square. See also articles by Redmond Barrett, published in a recent volume.

C. J.—If you are in any doubt as to the genuineness of the lens send it to the maker whose name it bears, and he will verify it if of his manufacture.

W. M. B.—Very finely powdered gum arabic when mixed with the suitable dry colour will answer. It will be better if it all be mixed wet, and when dry ground into a powder.

C. H.—The prints in question are lithographs varnished. They are, we believe, done on the Continent. Probably you will get them at some of the foreign fancy warehouses in the City.

B. W.—If your competitor is using the Royal Arms and styling himself "Photographer by appointment to Her Majesty" without holding the Royal Warrant—which we know he does not—he is liable to a heavy penalty.

M. E. SANDS.—The print named was done by Messrs. Goupil & Co., by their phototypic process, more familiarly known in this country as Woodburytype. Any of the firms who do this class of work will willingly undertake your order.

D. FRASER.—1. We can give you no idea of the comparative rapidity of the three lenses, as you do not say their focal length; without this the diameter of the largest stop is no guide whatever.—2. Better get an optician to make the alteration.

CHAS. WHITE.—The best method of preserving liquor ammonia is to dilute it with, say, an equal bulk of water, and then keep it in well-stoppered bottles in a cool place. In the diluted form it is much easier to keep uniform than when it is concentrated.

W. C. J. M.—A lens of thirteen inches focus will be too long for you to take full-length cabinet pictures in a studio only fourteen feet long. With a lens of that focal length you would get excellent results, but you could not employ it for full lengths.

COPY.—The plates sent are very unevenly coated. As the specks are exactly the same in each, we surmise that they were coated by a machine that did not do its work properly. Such plates should not be used for copying pictures, or, indeed, for any other purpose.

A. S.—The sulphide of silver ought to have subsided ere this. Possibly if you give it a vigorous stirring up for a few minutes it will then settle down. If the old toning bath contains any gold it will be precipitated on the addition of sulphate of iron. Perhaps the whole of the gold was taken up by the prints.

A. E. I.—Try the effect of fuming the paper with ammonia just previous to printing. If this does not prevent the loss of tone then must recourse be had to a different toning bath, or, perhaps, to another sample of sensitised paper; but we think that a vigorous ammonia fuming would answer every purpose.

W. G. S. inquires: "Can you please tell me of any means for removing nitrate of silver stains from linen?"—Yes, we can. Make a very strong solution of cyanide of potassium and dissolve in this nearly as much iodine as it will take up without becoming discoloured; apply this to the stains and they will disappear.

M. A. C.—You cannot prevent your neighbour building on his own ground, even if the workshop were to stop out the whole of the light from your studio. If your studio had been erected for twenty years you could then have claimed "ancient lights," and have prevented him from obstructing them. As it is you have no remedy.

J. W.—If you pack the prints merely in paper there is little wonder that they get marked with the obliterating stamp at the Post Office. The Post Office will not compensate for injury when the parcel is insecurely packed. The pictures ought to be placed between stout cardboard or millboard, then they would receive no injury from the stamping.

W. DIXON, 57, Elizabethan-street, Collyhurst, Manchester, writes: "Will some one assist me? I want to make enlargements 52×36 free from distortion in the margin; description and particulars of apparatus. I have pictures 13×9; I want negatives or transparencies to be taken from these pictures of a suitable size to secure the enlargements as above; description how to make or obtain apparatus suitable."

A. FOX inquires if any of the leading opticians mount their photographic lenses in aluminium. If not, why, seeing the great advantage of this metal in opera glasses and telescopes, on account of its lightness?—The chief reason, we imagine, why aluminium is not used for photographic lens mounts is that it would make them more costly, and purchasers would not care to give the enhanced price. Any optician would, no doubt, mount a lens in this metal to order if required.

W. CORNWILL.—It is a matter for the County Court; but we do not at all think you can recover. According to your own showing, you sent the print from the second negative on approval, and the portrait was not liked; therefore it was not to be expected that further copies would be ordered. Your customer did not commission you to take the second negative at all; that was a speculation on your part, and the portrait was not approved of. How can you substantiate any claim?

PHOTO-LITHO says he has recently been supplied with a mirror for taking reversed negatives, but with it he cannot get a sharp picture. The lens is a first-class one and produces excellent pictures when used direct, yet with the mirror nothing is sharp. He asks the reason.—It is clear that the mirror is not a plane surface, and should be returned. Before doing this, however, the setting should be examined to see that the glass is not fitted in too tightly. If this be the case the glass may be bent sufficient to alter its figure. The mirror ought to be quite loose in its setting.

CONSTANT READER writes: "I am sensitising my own paper, and made a bath for the same with oak frame and glass bottom. I cemented the glass in with shellac and a small portion of resin dissolved in methylated spirit. I have used it twice and find the silver bath becoming discoloured; it is now in a quart bottle, and to look through it it is the colour of dark sherry. I have tried carbonate of soda, also strong sunlight, without effect. Will this affect the albumenised paper by turning whites of prints yellow after fixing? Also, can you tell me how to clear my bath and what to do to prevent recurrence of discolouration? I may say the bath is quite transparent and clear but discoloured."—The discolouration arises from organic matter extracted from the albumen. Add to the solution a dessert spoonful of kaolin, shake well up, and in a short time the liquid will be colourless; decant and filter, and return the solution when again discoloured to the same bottle in which the kaolin is contained.

PHOTOGRAPHIC CLUB.—At the next meeting of this Club, August 14, 1880, the subject for discussion will be on *Blisters*. Saturday outing at Broxbourne.

RECEIVED when going to press:—*Mr. Pringle and Stereoscopic Photography*, by Mr. Abel Heywood, jun.; and Professor Stebbings on *The International Photographic Congress in Paris*. These in our next.

MACHINE-COATED FILMS.—From a sample packet of films received from Messrs. Samuel Fry & Co., Limited, we are glad to perceive that this firm is now employing machinery for coating celluloid films with gelatine emulsion, and very successfully so.

ANOTHER new wide-angle lens is being added to those already existing. Mr. Gotz has shown us one of a series which M. Suter is about to introduce, its characteristics being the including of a wide angle of view, with a stop larger than usual. We shall have more to say concerning it soon.

DEVELOPMENTS.—Under this designation Mr. T. H. Powell has brought out pyrogallie acid in a compressed form. Messrs. Marion & Co., Soho-square, are the sole agents for it. It is a highly convenient form in which to keep pyro, and we can strongly recommend it, as these little tablets were used by us, in another part of the world, between five and six years ago, and with invariable satisfaction. They are originally due to Dr. George S. Sinclair, of Halifax, Nova Scotia, who, annoyed at the numerous expedients to which he must have recourse to keep pyro in solution in a concentrated state, eventually got rid of his trouble by adopting compression; so machinery was made, and he had it compressed into small round tablets, each containing two grains. The Scovill Company introduced them commercially under the name of "Pelle-tone," being supplied in bottles containing one hundred of them. We are glad to see them introduced in this country under circumstances which will tend to their speedily becoming naturalised.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1528. Vol. XXXVI.—AUGUST 16, 1889.

NEGLECTED PROCESSES.—THE CHROMOTYPE PROCESS.

PERHAPS no process of photography was ever introduced with a greater flourish of trumpets than was the chromotype process; and, certainly, no better prints could be produced than were made by that method, and, what is more, they were permanent. The chromotype is an excellent process, yet it is truly a neglected one, and by this time, possibly, a forgotten one by many of those who paid heavy fees for licenses to work it; and that no longer than twelve or fourteen years ago.

The chromotype process, it may be explained, was introduced and patented by M. Claude Leon Lambert, a Frenchman, in 1874. It is a modification of the carbon process, and it was for a time, without doubt, the strongest rival that silver printing, for ordinary work, ever had. Its result could not be distinguished from silver prints, and any colour could be obtained. Certainly, M. Lambert did produce, from given negatives, better prints than they would yield in silver. Furthermore, he threw out the challenge—so did others—that he would produce, from any negative, not only as good but better prints than could be obtained in silver. No one took up the challenge.

The late Mr. Jabez Hughes—always an enthusiast in permanent photography—although he had more than once essayed the carbon process, for every-day work, by different methods, such as developing on zinc plates, varnished glass, Johnson's "lac paper" (flexible support), &c., was compelled to abandon it in the end. When, however, he took up Lambert's modification he never relinquished it, and up to the time of his death, we believe, all the prints issued from his establishment were made by the chromotype process, silver printing being, for many years, entirely abolished. Chromotypes were usually printed with a masked and tinted border, but Mr. Hughes did not adopt this style, at least to any extent; he simply produced plain prints like those on albumenised paper. The chromotype process is still worked, and extensively too, by a few houses. We have in our mind just now a town in the West of England where, perhaps, more chromotypes are turned out than in any half-dozen other towns in the kingdom put together.

The chromotype process, it may be explained for the benefit of the younger recruits in the ranks of photography, differs materially from the carbon process as ordinarily worked. In this method the exposed tissue, instead of being developed on a repellent substance, as in the case of the waxed surface of a rigid or flexible support, is developed upon a soft and spongy film of collodion, which assimilates with it and forms part of the finished picture.

The process is worked as follows:—A glass plate is coated with collodion, and when it has set the glass is placed in water to wash out the ether and alcohol. Then the exposed tissue is squeegeed on to the collodion film, and afterwards developed in the ordinary way. After it is finished the transfer paper is applied, as in the usual method of working, and when dry the picture is stripped off the glass, of course collodion and all. The print, when removed, possesses all the high gloss of a silver print which has been "enamelled." If it be desired to retain this high gloss the mount must be attached before the print is taken from the glass, in the same way as enamelled prints are mounted. It will here be seen that when enamelled pictures are required the chromotype process is about the simplest method of producing them. If the prints are simply mounted and rolled after they are stripped from the glass, they will possess about the same degree of gloss as that of double albumenised paper. If less glaze than this be desired, it may be obtained by merely damping the pictures prior to attaching them to the mounts.

From the above brief description of the process it will be seen that the collodion forms an integral part of the finished picture, the same as it does in making carbon transparencies. The collodion, in fact, here serves a double purpose. First, it tends to hold together the more delicate and tender portions of the image during the development. Second, by reason of the glaze conferred by the film, the shadows are rendered as transparent as they are in a silver print. The chief objection to carbon pictures for small work, as ordinarily produced, is the lack of transparency in the shadows. But this is completely avoided in the chromotype process.

Why, it may be asked, with these advantages, coupled with that of permanency, is it that the chromotype has become such a "neglected process?" This is a somewhat difficult question to answer at the present time. At one period the process was hampered by a number of patents, and heavy fees were charged for licenses; also the special tissues used by M. Lambert were only supplied to licensees, although other tissues would have answered quite as well. It was the colour alone that constituted the speciality. Again, exclusive licenses were granted, and it was asserted that some were purchased for certain districts without any idea whatever of working the process, but simply with the view of preventing others from doing so, and thus avoiding competition. Furthermore, an outcry was raised that some of the pigments employed for the special tissue were fugitive—cochineal colours being used. However, there were other tissues in the market at the time of a very similar, if not identical, colour, in which alizarine, a more permanent pigment, was used.

The above have, from time to time, been put forward as reasons why the chromotype process was, and is, so little worked. Now, however, all the chromotype patents have long since expired; so have all those in connexion with carbon printing generally; hence chromotype can be worked without let or hindrance. Still, the process is only worked to a very limited extent commercially. The real reason for this, we strongly suspect, is this: It is somewhat more costly, and at the same time more troublesome, to work than silver printing.

THE FRENCH CONGRESS.

THE voluminous character of the programme of the Congress now proceeding in Paris, together with the accompanying "reports," prevented our appending a few remarks of our own, as we had intended, before the opening sitting. As, however, the proceedings, as so far reported, are of a comparatively unimportant character, we may still carry out our original intention.

The programme has already been discussed by the members of the Photographic Society of Great Britain, and, as was only to be expected, elicited some rather uncomplimentary expressions of opinion. France, as supposed to be *par excellence* the nation of courtesy, might have been expected to have been a little more liberal in its hospitality to the foreign members of the Congress, instead of charging them a heavy subscription in the first place, and leaving them to look after themselves as best they can.

But it is in the capacity of self-constituted promoters of the Congress, which was to be "international," that the exhibition authorities have laid themselves open most seriously to criticism. By what authority, we should like to ask, can they call their decisions "international" when the meetings are held entirely without the co-operation of any *official* foreigners, and when, as reported by our Paris correspondent, the total number of "strangers" present at the first meeting did not reach half a dozen?

Then, again, by what authority, to say nothing of the want of ordinary courtesy displayed, do the self-appointed managers propose to discuss, and possibly frame, laws upon certain questions that have already been carefully studied by our own Photographic Society, whose decisions have been generally accepted throughout the world? Surely the least that could have been expected would have been some direct official communication with the Photographic Society of Great Britain, as well as the most representative societies of other countries, with the view of securing the official attendance of delegates.

In the case of our own Society, the omission was a most flagrant one, and we do not hesitate to say that in the event of the present Congress arriving at decisions differing from those previously come to in England, the Society will have a perfect right to repudiate them, even if photographers outside France show any inclination to follow a false lead.

The fact appears to be that our neighbours are so unduly elated with the success of their exhibition, that they have slightly forgotten themselves. Not only is Paris France, but France, they seem to think, is the world. One cannot help thinking of the fable of the frog and the bull—a particularly appropriate one by the way—and hoping that our lively friends may not meet the same fate as their ancient prototype.

With regard to the various questions to be discussed, it struck us on reading the programme issued, and the very

lengthy reports accompanying it (of which we gave brief abstracts a week or two since), that the "authorities" had made up their minds, once for all, before the start, and intended to carry their own ideas. Such appears undoubtedly to be the case as far as things have gone up to the present, as reported by our Paris correspondent. On question seven, we are told, "the propositions of the commission were accepted and voted without great difficulty," while as regards question eight, though our reporter says "many difficulties came in the way," they seem to have been surmounted with singular ease—with little more than a quotation or two from the official programme.

In reply to an attempt to retain the name of Woodbury in connexion with the process he invented, the President is stated to have said, "That names of inventors could *no longer* be tolerated; photography takes *no longer the name of Daguerre*." The italics are ours, and we read the reply to mean that if Niepce, Daguerre, and Poitevin could be pressed into service for the naming of modern processes, the decision would be different. But the sentiment with regard to suppressing inventors' names was, if we remember rightly, expressed in the programme, or rather in one of the reports. Similarly, "studio jargon" (*jargon d'atelier*) was condemned, and in opposition to Mr. Warnerke's proposal to legitimise the term "hypo," the President decided that "this shop language cannot be tolerated." Probably the actual words employed were the same as those we have already quoted; if so, they are adhering closely to the programme.

The information to hand up to the present is too scanty to form a basis on which to found any serious opinion of the justice or otherwise of the conclusions. Question seven relates to "Uniformity in the expression of photographic formulæ," and, as we learn, the proposals of the Commission have been accepted *en bloc*. These consisted in the suggestions that a uniform system of weights and measures should be adopted, and that solids should be expressed by weight, and liquids by volume. The matter being already settled, who will doubt that the decision is in favour of the French or metric system, and, such being the case, who, be he ever so sanguine, will expect the recommendation to be adopted by English photographers? If this may be taken as a fair prospect of the probable decisions on other questions, we venture to think the labours of the Congress will remain a dead letter so far as this country is concerned.

The eighth question deals with "Uniformity in the denominations of photographic processes," and here the recommendations of the Commission consisted of, first, the abolition of "studio jargon" already referred to, with which we are in perfect sympathy. We cannot at all agree with our friend Mr. Warnerke's proposal to make "hypo," "pyro," *et id genus omne*, recognised scientific terms; they are bad enough in conversation or in ordinary current photographic literature, but would be entirely out of place in more serious works, and therefore we think the proper course has been adopted. With regard to the nomenclature of processes, a systematic application and combination of terms was proposed which will give to the titles of photographic processes a descriptive and self-explanatory character similar to that prevailing in chemical nomenclature. This, at the present time, is of vast importance, and seeing that no organised attempt has been made in that direction previously, we can find no fault with the adoption by the Congress of the suggestions laid before them.

Of the remaining questions, it will be as well to say little.

until we hear more; but we would point out, especially with regard to the question of standard flanges, stops, screws, &c., that these, as established by the Photographic Society of Great Britain, have been adopted already over the whole world, and it will be on no light grounds that the present Congress will be able to alter them. The Whitworth standard screw threads are, we believe, adopted in France, so there can be no difficulty on that score to urge against the acceptance of British standards. If it were otherwise, the French opticians who imitate so readily the *curves* of English and German lenses would be equally able to imitate their screw threads, if necessary.

As regards the standard light, we have nothing in connexion with photography more reliable than the standard candle, or the Warnerke sensitometer, both of which are admittedly defective. However, as Mr. Warnerke is present at the Congress, he will no doubt take part in the discussion, not only on his own behalf, but also as a member of each of the sub-committees of the Photographic Society of Great Britain which have had the trouble of studying these questions previously.

At present we can only hope that the decision will be generally such as may be, if not accepted absolutely, at least used as the basis upon which a really authoritative Congress may work.

EVERYTHING is now ripe for the opening of the Photographic Convention of the United Kingdom on Monday evening next, the 19th inst. The various committees have completed their labours, with the result that there will be a fine collection of pictures and apparatus. Several papers on the topics of the day will be read, and highly attractive excursions have been arranged. These, together with choice lantern entertainments, and an evening lecture by Mr. E. Muybridge, during which he will show his renowned "Animals in Motion" series, afford some idea of what has been prepared for the members of the Convention and their friends. The proceedings will be opened by a *conversazione* on Monday, at 6.30 p.m. Mr. Muybridge's demonstration is fixed for Wednesday, and the annual dinner for Friday.

ANENT the American Convention, which was held in Boston, U.S.A., on the 10th inst. and following days, just when ready for going to press, we have received the *Report on the Progress of Photography in America* during the past year, by Mr. W. Lincoln Adams; and we have also received a medal which was struck by the enterprising Scovill-Adams Company, in commemoration of the Semi-Centennial of Photography, and presented to the members of the Convention. It has a fine head of Daguerre on one side, and a suitable inscription on the other.

WE have repeatedly been asked whether it is not possible to obtain celluloid suitable for sensitive films in this country, it being a well-recognised fact that its chief seat of manufacture is Newark, N.J., a city about eight or ten miles distant from New York. We are pleased to be able to inform such applicants that S. Guiterman & Co., 5, Hart-street, Wood-street, E.C., are English agents for it. From this firm we have received sample sheets, which, when cut up into smaller sizes, we have coated with both gelatine and collodion emulsion. As the sheets measure 50 x 20 inches, and are capable of being cut with remarkable facility, photographers will discover several uses to which this substance may be applied other than their primary great use, that of serving as a support for the negative film. Among the samples are also some of a fine opal character.

THE Newcastle meeting of the British Association is expected to be of exceptional interest, and already active preparations are being made for the due conduct of the various meetings and excursions.

The presidents for the various sections are:—Captain W. de W. Abney, R.E., C.B., F.R.S.; Sir J. Lowthian Bell, F.R.S.; Prof. James Geikie, F.R.A.; Colonel Sir F. de Winton, K.C.M.G.; Prof. F. J. Edgeworth, M.A.; Mr. William Anderson, M.I.C.E.; Prof. Sir W. Turner, F.R.S.

THE evening discourses do not promise anything of photographic interest, but we have little doubt that the excursions will be well accompanied by camera and lens.

APPROPOS of this, the question has been put, "Has the introduction of gelatino-bromide plates been an advantage or a detriment to the art?" and the replies have been by no means of a unanimous character. One experienced and clever amateur of our acquaintance lately expounded his views in a very pronounced and decided fashion. "It has degraded the art," he said, "and has not advanced photography one iota. It has advanced photographers, if giving to any one of common sense the power of making a presentable landscape with a day's training at the work may be called advancing it. I used to be proud of my camera, and of my skill in using it, but now I am ashamed of it, for every boy and girl in the country can do in ten minutes what it took me years of practice to attain proficiency in, and in consequence photographic kits swarm over the country, and are a nuisance and an eyesore," &c.

WE have noted this speech because it represents the feeling of so many old hands who with labour and loss learned how to make dry plates, but whose knowledge is now simply a dead letter—useless lumber, we have heard them call it. Contrariwise, we are bound to remember what a source of keen pleasure to hundreds is the modest kit so scorned by the amateur we quote, and as to photographs themselves, the walls of the exhibitions tell us how many more good photographs are now produced than within a very short time ago was the case, and we do not hesitate to assert that pictures of great merit have been shown that before the advent of gelatine were impossible of achievement.

THE use of hydroquinone has quickened the demand for caustic alkalis in development, and solutions of soda and potash are now common enough; but it should ever be remembered that when exposed to the air the caustic forms of soda and potash are capable not only of absorbing moisture from the air, but carbonic acid also. The result of this would be that the alkalis would gradually become converted into carbonate, and, contrary to the general opinion, apparently lose a portion of their power. This will be the case not only with the fixed alkalis, but also with solutions of ammonia, unless thoroughly sealed against the action of the atmosphere. The latter chemical would thus lose strength in a double fashion—first, by evaporation, and, second, by neutralisation.

AMMONIA, as we have often pointed out, is far better stored when diluted by being mixed with an equal bulk of water, so as to lessen its tendency to volatilise, which is the greater the greater its concentration. Some photographers store it in bottles secured with a cork; but it is always better to employ glass stoppers, as, in the first case, cork is apt to quickly become rotten, and, in the next, it rapidly loses its protective power against the diffusion of gases. On the other hand, unless special care be taken against its action, any little extra rise of temperature may cause the stopper to fly out, possibly during the absence of the owner, under which conditions the liquid will deteriorate (by losing strength) in a remarkably rapid manner.

IN our own practice we smear the stopper with vaseline, which forms a very efficient protective against evaporation, and if unusual heat at any time should cause sufficient pressure to remove it, the stopper will rarely become ejected—it will simply act as a relief valve and drop into its place again.

THIS vaseline protection, too, is most excellent for bottles containing solution of pyro and sulphite which have a most unpleasant knock

of becoming very tightly fixed after a few days' storage. This, no doubt, is owing to the fact that the oxygen of the air is quickly absorbed by the pyrogallie, with the result that the outer pressure is greater than the inner, and so has to be overcome in removing the stopper, which also, by reason of the pressure, tends to become locked also. The effect, whatever the cause, is very annoying: a slight smearing with vaseline is a complete cure.

THE OCCASIONAL FAILURE OF EXHIBITIONS.

It must be within the experience of all regular exhibitors that it occasionally happens that an exhibition, opening under what might be reasonably considered the most favourable auspices, is from some apparently inexplicable cause a dead failure. Let us try if we can discover some of the common causes of want of success, and perhaps a consideration of them will suggest means by which they may be avoided in future.

The first thing to consider is the question, What is required? What are the objects for which exhibitions are instituted, and how far are they carried out?

The first series of photographic exhibitions, promoted by the Society of Arts before the formation of any photographic society, was intended to diffuse a knowledge of the new art throughout the country. It is, of course, no longer necessary to prove that such a thing as photography exists. The first great object of the exhibitions now held should be to show year by year the advances made in the many departments of the art; the second aim, to encourage and teach those who are beginning and those who are making progress; and the third purpose should be to get together such a collection as will show all the best work done since the last exhibition, and the sight of which shall be worth the fee charged for admission. Perhaps the third object includes the first and second. I think it will be admitted by all that these are the chief excuses for general exhibitions—I exclude from my argument the very useful and interesting semi-private gatherings of local societies—yet the tendency of the management of some recent exhibitions seems to be not only towards excluding the best work, but to prevent any ambitious photographer from doing his utmost to produce anything out of the common run of every-day production. This is done, I admit, from the best motives, the chief of which is the encouragement of new work, but I cannot help feeling that the means employed will tend in the end to impoverish exhibitions, and compel them to deteriorate into such shows as can be seen in the shop windows of professional photographers, and the albums of amateurs, in nearly every town in the kingdom. The apotheosis of mediocrity.

The time of year at which an exhibition is held has much to do with its success. An exhibition held in September or October will be filled with the newest work, while one opening in June will be too early for most of the work of the year, good or bad, and will have to be content with the productions of former years, which have been the rounds of the exhibitions all over the country. And if there is a rule excluding from competition all pictures which have taken champion prizes, all that can be expected cannot, of necessity, be of a higher class than that below the highest. An example of this kind of failure is to be seen in the exhibition now being held at York. No exhibition could have been collected together under better, more enterprising, or more liberal management. It was well advertised, judicious pressure was put on exhibitors to contribute, and gold and silver medals were offered lavishly. Yet what is the result? The poorest show that could be called an exhibition, consisting almost entirely of pictures that have been seen dozens of times, padded with frames of indifferent photographs that should never have been accepted; so poor a show that the judges were, perforce, compelled to withhold several of the medals. And to make matters worse, the best of the old pictures were absolutely excluded by an addition to the rules for the champion classes, which excluded all champion pictures. The champion class was a well-intended invention, designed for the encouragement of those who could not do the best work, by removing prize pictures to a competition among themselves, leaving the ordinary medals to be competed for by those works which came next in quality; in other words, by the best that were left after the best were removed.

There was nothing particularly objectionable about this, except that it tended to too closely follow the example of those schools where every little boy gets a prize whether good or bad; but when medals are offered in a champion class, as they were at York, "limited to one photograph from each competitor which has not taken a champion prize elsewhere," it is a direct bid for second-class work, and it is not to be expected that the pictures which have taken first prizes would be contributed. Besides, what becomes of the meaning of the word champion. And thus the exhibitions are deprived of those very pictures which one would have supposed would have been the greatest attraction to visitors.

As regards the time of holding exhibitions, the season may be said to begin in September with that of the Royal Cornwall Polytechnic Society. This Society was one of the first to offer medals for photographs, and has always commanded the pick of the new photographs of the year. This exhibition may be called, in comparison with some others, small and local, but it has always been supported by the chief exhibitors, and is one of the most interesting shows of the year; and, moreover, it is free, there being no charge made for space. It has never had a champion class, but it has tried another method of handicapping, which consisted in not allowing a taker of a first prize to take another medal of any kind for three years. It was actually a misfortune to take a first prize the first year, as it placed the competitor out of the competition for a time, whereas if he took a second silver, equal in value to the first only in name, he was eligible to take a first the following year. This arbitrary rule failed, as any methods, however ingenious, of preventing the best competitor winning always will do in the long run, and the Society very wisely gave it up.

The next exhibition of the year in point of time is certainly the most important of the season, both for size and quality. It is that of the Photographic Society of Great Britain. To this exhibition, it is not too much to say, everything of importance is sent. And this invariably, with the exception of last year, when the Council tried the experiment of withholding the usual medals which preceding exhibitors resented, and there was a marked falling off in the number of pictures sent, and, in the opinion of many, in quality.

Now, when it is considered that about twenty medals are awarded at each of the two exhibitions I have named, it must be easily seen that a very large proportion of the best pictures of the year have been medalled, and, according to the new rules, thrown out of the running for any but the champion classes; and if the York addition to these rules is to be continued, every one of those pictures that take a champion prize is debarred from further competition. No further handicapping is possible.

After the London follow the Provincial exhibitions, in quick succession. Now it must be admitted that the chief object of these exhibitions should be, and is, as a rule, to get together all the best pictures of the time, whether they have been exhibited elsewhere or not, in order that the people of the district may see for themselves what is being done in the art; that photographers may judge for themselves the direction in which they would prefer to aim and the work they would emulate; and, finally, that the exhibition should be worth the admission fee and be also a financial success. Yet how do they go about it? They put all the obstacles possible in the way of the best pictures by placing restrictions on them. The result is that many of the best pictures are never seen in the provinces. Few photographers produce more than half a dozen of their best in the year, and fewer have any of their first-rate work left unexhibited after the London Exhibition.

As an exhibitor, I have, personally, no objection to the champion classes, when they are not made absurd by restricting them to pictures which have never taken champion medals; but if the object is to get together the best collection of pictures, they are a mistake.

Then follow a few minor causes of failure, the chief of which is the large entrance fees sometimes charged. Photographers, especially amateurs, find the expense of frames, packing cases, carriage, &c., quite enough without having to pay for the pleasure of lending their pictures, as many do, without the hope of any return in the shape of sale or award. And even medals can be bought too dear at times. For instance, I should have been glad to send to the present Paris Exhibition, but when I was asked to send also a cheque for 5*l.* for a small space, I concluded the game was not worth the candle.

Other causes of failure are the time, sometimes months, for which their producers have to lend their pictures, and doubtfulness as to who are to be the judges. Not that I think much of this last cause, for, as far as my experience goes, the judging is always fairly done.

H. P. ROBINSON.

CURRENT COMMENTS.

POSTAL DAMAGE TO PHOTOGRAPHS.

THE amount of photographic damage caused by postal transmission seems to be rather on the increase than otherwise. I hear much of it, and undoubtedly, by your answer to "F. W.," it must only be a sample of one of the petty grievances which do so much to annoy business men. After hearing many complaints about the unavailing nature of card or mounting boards to prevent the obliterating stamp mark of the post office passing through and destroying good, well-finished work, I was induced to try *thin wood*, and, after the practical testing of it for a number of years, it has proved a perfect cure. Many of the complaints were of single pictures, which had the mounts creased and broken by postal rough usage, as well as by the mark of the impressed stamp; but since the adoption of this plan by several of the principal firms they have entirely ceased to complain.

As I do not remember seeing any notice of this, it may prove a small public service to describe the *modus*. The timber used is the finest yellow pine, which is much better adapted by its nature than the cheaper white pine for this purpose, and cut from three-inch boards, with the perpendicular frame saw (not the circular, which makes a much rougher job), into eighteen or twenty thicknesses to the three-inch board. The outside slabs and any blemished ones being rejected, they are then cut to the required size, keeping the grain of the wood running lengthwise with the upper side, on which the address is placed, and crosswise on the lower. The thickness is about that of mill or mounting board, and the weight much less, while, from the spring given by the rough-sawn surface, its resisting power to the stroke of the stamp is much greater. The cost should be no more, if it is not less. "F. W." and others are welcome to the hint.

REVERSING NEGATIVES BY USE OF MIRROR.

In reference to the use of a mirror for reversing negatives, in addition to your own excellent suggestions, this may be noted that it is almost impossible to get a patent plate mirror of any large size to reflect truly. The body of the glass being blown, it is helplessly twisted in the making, and it is in addition much more subject to strain than cast glass, so much so that it will not do for the purpose; yet, strange to say, from its thinness and lightness, that is the kind most invariably stipulated for or used. If the thicker and heavier British or foreign plate glass is taken the reflections will be truer, but from its thickness, and being silvered on the back of the inner reflecting surface, and the separation and duplication of reflecting surfaces, two invariably, and occasionally a third secondary, image of the object becomes visible in certain lights. This is more apparent with some makes of glass than with others, and it is painfully apparent when the surfaces of the plates are not truly parallel and plane. Also the body of the glass is by no means free from strain, as those who have to supply the glass for lighthouses become painfully aware of, in the shape of rejected plates—Trinity House and the Board of Northern Lights being rigidly strict in this respect; I have thought needlessly so.

The only real cure and way out of the difficulty with a mirror, if it must be used, is to silver the mirror on the outer, not the inner, surface of the glass by the pure silver—not the mercury and tinfoil or quicksilver process—and polish the surface as is done in the case of glass specula for reflecting telescopes. This will give a true and sharp image, capable of the most accurate focussing, &c., the reflected image being on the surface of the plane-silvered mirror, there can be no chance of double reflections. Very great care must be used in using and keeping such mirrors.

My own rather extensive practice, for the purpose wanted by "photo litho," has been to use absolutely speckless and spotless patent plate glass for the negatives, and to take the picture through the glass, making the proper allowance in the focussing for the thickness of the glass used. The reason for insistence on pure fine glass is that every air-bubble, speck, or spot in the body or on the outer surface of the glass repeats itself, and generally in a distorted form, in the negative, and so tends to spoil the result.

In the current number of the *Beacon*, noticed in THE BRITISH JOURNAL OF PHOTOGRAPHY for August 9, our friend Dr. Nicol, on making a few rather jocular remarks on spirit photography, and how it might be done *apropos* of the photographic transparency of

some seemingly opaque media, quotes from an article by Mr. S. Ball in a recent number of *Macmillan*: "When the Great Eastern was in Dublin, my friend, Mr. H. B. White, took some pictures of the vessel. She had previously come from Liverpool, I believe, where her colossal hull had apparently been made the vehicle of a gigantic advertisement. Before coming to Dublin, the inscription had been completely obliterated by liberal applications of coal tar, yet the photographic plates *saw through the tar*, and showed conspicuously every letter of the advertisement."

In this connexion, I may relate a similar and quite as authentic an instance—similar, but not quite the same. On the east wall of the General Register House in Edinburgh, at one time, but it must have been many years ago, there was painted in black letters on the polished ashlar sandstone of the curtain wall which encircles it on that, the south, and west sides, an inscription warning people against defacing it under a penalty—that of being fined sixpence. I had seen this when a boy and young man. It had been removed at some time by order, and the paint washed and polished off, so as to be invisible. But one day, while photographing a twelve-by-ten view, that side of the curtain wall came in as a portion of it, and to my amazement the negative showed the erased inscription perfectly visible. A still more curious feature of the case is, that when this was spoken of there had been noticed by many people that, after foggy weather in winter-time, the same inscription could be seen projecting from the wall in letters of hoar frost, and varying from quarter of an inch projection downwards to only the appearance in white on grey on the wall. Whether it keeps up its antics still, or has got worn out from old age and decay, I do not know. As the announcement was rather a ludicrous one, the latter circumstance was much talked of. The letters seemed to have been done in common black oil paint. THERE is a nut to crack for some of your speculative and transcendental readers.

W. H. DAVIES.

THE following four papers are from the "Grand Convention Number" of the *St. Louis and Canadian Photographer*. We are not quite certain whether these are special contributions to our American contemporary in anticipation of the Convention, or are advances of papers to be read at the Convention.

PRACTICAL THOUGHTS ON SILVER PRINTING.

By J. R. SWAIN.

IN hot weather the positive bath should be cooled to about seventy degrees before silvering the paper. Be sure to silver long enough to coagulate all the albumen. No danger of over-silvering. In experimenting the writer silvered six sheets respectively—four, six, eight, ten, twelve, and fourteen minutes on a fifty-grain bath. No difference could be noticed in the finished prints. But in printing, the three last had a greater tendency to turn yellow, but all bleached out alike in the toning and fixing baths. From two to three minutes is about right in summer, and three to five in winter.

If the paper is very dry the time of silvering should be increased. There is nothing gained by trying to dampen the paper before silvering, except probably a minute's time to each sheet, and even that is doubtful.

The paper must be bone dry before fuming, and in damp weather should be dried again after fuming. In very hot, damp weather the paper has a great tendency to turn yellow while printing. The only preventive is to see that the negatives and pads are thoroughly dry and kept dry while printing. Three or four washings are sufficient before toning. No need of any acid or salt being added to either to redden the prints; this is only a waste of time and labour. A small pinch of salt, say fifteen grains to each eight ounces, should be added to the toning bath. The toning bath is simply gold and soda with the salt as stated above. One grain of gold is required for each sheet of paper to be toned. Some claim to be able to tone five or six sheets with one grain of gold, but experience teaches differently.

It is a good plan to learn to tone in a darkened room by lamplight, and to judge of the tone by looking *through* the print instead of looking *at* it. More even tones can be secured in this way, and if one is late, toning can be as successfully done after dark as in daylight. Whatever is done to prevent blisters must be done between toning and fixing. The recently published acetic acid bath seems to be the best at present. The prints after toning and before fixing should be washed through two changes of water, then immersed for a few minutes in a bath of acetic acid two ounces, water one quart, washed once or twice and fixed as usual. Not a single blister has ever appeared in the writer's hands after this treatment. The acid toughens the albumen and gives the prints a rich, bright appearance.

LARGE DIRECT PORTRAITS VERSUS ENLARGEMENTS.

By G. HAMNER CROUGHTON.

ONE of the first things that impressed me on coming to this country was the much larger size of direct portraits made by photographers as compared with those made on the Continent. I had been but a few months in this country when I went to the Convention at Cincinnati, as special correspondent to THE BRITISH JOURNAL OF PHOTOGRAPHY, and in noticing the exhibits I laid much stress on the fact that a large part of them were of heroic proportions. 20 x 24 was small to some that were there exhibited, which, as far as I can remember, must have been quite forty inches in length. I remember making inquiries of the photographers who exhibited these mammoth pictures as to the sale they had for these large portraits, and, without exception, I was told they did not expect to be reimbursed for the expenditure for the apparatus necessary to make such large pictures, that although they might pay as an advertisement, there were very few people who would pay a sum large enough to make it worth the photographer's while to produce such large portraits.

This, in itself, would be sufficient to prevent photographers from catering for this class of work, for if a thing does not pay in dollars and cents, it is not likely to be pushed. Apart from the business point of view, which, after all, is the most important, comes the fact that large direct portraits, when hung at a proper distance for viewing large work, show a heaviness in the shadows that is to an educated eye very disagreeable. Then another objection is that lenses made for such large work must necessarily be of short focus, and exaggeration of the near planes must result. In some of the large heads exhibited this was most distressing, the nose being broadened and enlarged out of all proportion. Next, is the fact that few people will sit sufficiently long, in these days of instantaneous processes, to get a properly exposed negative, and for young children it is extremely difficult to get anything satisfactory over a certain size. Then, again, the price that must be charged for these large pictures, to make it pay, is as much as would buy a well-executed crayon picture. Very few people, who know nothing of the difficulty and expense of obtaining good, large, direct pictures, and the amount of time to be spent in retouching the negative, &c., care to pay as much for what they would call only a photograph as they would pay for a crayon if well executed.

These considerations will always keep the production of this class of portraits in a very small minority, and enlargements will be the rule, with large direct portraits the exception. The advantages of enlargements over the large direct portraits are very many. In the first place, the expense for large apparatus is saved; secondly, it is not necessary to use a short-focus lens for making a cabinet negative; therefore, there need be no exaggeration or false perspective. The expense of large plates—a very considerable item—is saved, and the photographer can satisfy his sitter in expression, light and shade, &c., upon a cabinet-size plate, before attempting to make his enlargement. For children there can be no question as to the advantage of enlargements. To get a lively child it is necessary to use the quickest possible process, and that can only be obtained with small sizes, and it means a very different thing to spoil two or three 5 x 8 plates to having to do the same thing with the larger sizes. Then, again, most of the large pictures are wanted from portraits of deceased friends or relatives, where there is no question of making large direct pictures. Therefore it is necessary that photographers should keep themselves well posted in all that pertains to the production of enlargements. In an establishment where there is so much small work that it leaves no time for anything else this would be of little importance, but in the majority of studios, where there is a considerable amount of time which can be used to some advantage, a method of producing large pictures from small negatives which every one can use, and which requires no expensive or unusual apparatus, is a *desideratum*.

This is either by the gelatino-bromide paper or by the carbon process. This last, however, necessitates the production of an enlarged negative; the results, however, are very fine, but they scarcely pay for the extra trouble in production. The gelatino-bromide process of enlargement is simple in its workings, satisfactory in its results, and lends itself either to simple mending or highly finishing in crayon, or other methods of working. Any ordinary portrait lens will make an enlargement, and there is no other apparatus needed than cannot be found in any ordinary photographer's studio, or, if not, can be made, either by the photographer or a carpenter, for very little expense.

Therefore, there can be no question that, taking all things into consideration, it is better for the photographer to fit up an enlarging apparatus than to spend a large amount of money in buying large lenses, heavy cameras, and all the troublesome accessories needed to produce large, direct pictures.

HOW TO SUCCEED.

By P. ENSLY.

To those who are striving to master the problems in photography and fit themselves for honourable competition for first-class work, let me say in general work adopt and study to master such formulae, and such only, as have been well tried and proven to be reliable. Let experts work out the processes, and when they have made a success of them it is then time for the average photographer to take them up. It is well enough to experiment a little during leisure hours, and help to bring out new ideas, but, when doing regular work, use the formulae which you are best acquainted with, and never discard an old formula for a new one until the new has been well tried and proven to be of greater value than the old, remembering, however, that formulae often have to be varied to suit circumstances.

Nine-tenths of the difficulties in using dry plates, as well as albumen paper, may be avoided by the manipulations. Think not to succeed by sticking to an iron-clad rule under all circumstances. For instance, negatives cannot be treated the same in cold and hot weather. Neither can they be treated the same when over and under exposed. Again, albumen paper must have very different treatment in cold from what it requires in hot weather, also the management must differ in wet and dry weather.

Thanks to our great leaders, they have told us plainly just how and what to do, but there is some knowledge indispensable to success that is not in the market to be bought and sold. It is only acquired by hard study and close observation—in other words, by experience. The successful operator can tell the moment the image makes its appearance on the plate whether everything is working right, and portions his chemicals accordingly. The printer can do the same. To the close observer, evils that beset us in our every-day work have a warning voice; like storms, they never burst upon us without clouds first appearing.

He who loves the work, and patiently and perseveringly studies it for the love of it, will have his labours crowned with success.

THE PIZZIGHELLI PLATINOTYPE PAPER.

By F. C. BEACH.

HAVING experimented lately with the imported paper made in Germany after the special formula of Pizzighelli, I have found it to be remarkably simple to work, and predict a large consumption of it in the near future. It appears to be slightly slower than silver paper, the usual time of printing occupying about twenty minutes in a bright sun. But its rapidity in printing is increased if the sensitive surface is slightly moistened by breathing on it, or holding it over the steam from hot water, or at the mouth of a tea-kettle, before printing. Its simplicity of manipulation is one of its chief merits, and it will keep if encased in a tin box or a wood box well waxed, or in a waxed paper bag.

Taking a sheet from the package, it is slightly puzzling to rightly place it in the printing frame in a room illuminated with yellow light, since both sides of the paper look alike, and it also lies flat. The better plan is to glance at it in shaded white light to know exactly which is the sensitised side.

In printing, I have found that unless a pad, either of felting or a double thickness of paper, is laid over the back of the sensitised sheet, so as to be between it and the back of the printing frame, the air will, in some way which I have not yet been able to explain, affect the paper at the joint of the printing-frame back in such a way as to cause a light streak across the picture.

The printing is carried only as far as it is desired the picture should be. There is no guess work about it. When it is done it is simply put into water containing a trace of muriatic acid, which in the course of two minutes dissolves out the yellow, unacted-upon salt, and causes the picture to appear more brilliant. Thus in two minutes the picture is fixed, washed for three minutes more in one or two changes of water, dried between blotting paper, and is then ready to mount. The result is an absolutely permanent photograph, one that looks like an etching, and is particularly agreeable in comparison with the ordinary glossy silver print. The tone is a brown black, and can probably be varied by the degree of moisture imparted to the surface before placing in the printing frame. The paper is specially adapted for black-and-white subjects and large landscapes.

For the amateur it will be the paper, as no manipulation is required, beautiful prints being so easily made. As a quick means of supplying artistic proofs, it will be an advantage to the professional photographer. The practical success of this paper in our half centennial of the progress of photography is one of the minor things to which our attention is called.

TO REMOVE YELLOW STAINS FROM NEGATIVES.

A CORRESPONDENT in Sivas, Turkey, says it will require several days' journey in his distant land to consult a professional photographer in regard to the information he seeks, and asks the *Scientific American* to tell him how to remove successfully a yellow tinge on one end of a valuable negative.

The cause of the stain is probably due to insufficient fixing of the plate originally. Hence the treatment is different than if it was a pyro stain caused during development. The latter stain can be removed by immersing the plate in a clearing solution composed of—

Alum	2 ounces,
Citric acid	1 ounce,
Water	10 ounces,

for several minutes. The plate should be soaked in water for ten minutes prior to being placed in the above, provided it has been dried and printed from.

Another formula for removing silver stains produced in printing from ordinary silver paper is to mix two solutions—

A. Sulphocyanide of ammonia	$\frac{1}{2}$ drachm.
Water	1 ounce.
B. Nitric acid	$\frac{1}{2}$ drachm.
Water	1 ounce.

Mix equal parts of A and B fresh for each negative, and apply to stained portion, or immerse the negative in the solution. When the stain disappears the negative should be washed, and followed by an application of a saturated solution of chrome alum.

When the stain is caused by insufficient fixing, it is said to be removed by converting the silver in the film into an iodide, and then dissolving out by cyanide of potassium. The method recommended by Mr. Drake is as follows:—Soak the plate for five minutes in clean water, meanwhile make a solution of iodide of potassium, twenty grains to the ounce of water, now put the plate in this solution, and let it stay for ten minutes. If the stain is very old, keep it in for half an hour. Now dissolve half a drachm of cyanide of potassium in one ounce of water. Take the plate and put into this, and gently rub the stains with a tuft of cotton wool (absorbent filtering cotton will do), free from grit, until they are quite gone. If the stains are very old, make the solutions stronger and soak for a longer time.

The stain due from insufficient fixing is usually very difficult to remove. A plan which we have thought of, but not yet tried, is to change the colour by slight intensification.

First immerse the plate in a weak solution of bichloride of mercury and water until the film commences to bleach. Then wash and immerse in a solution of cyanide of silver similar to Monckhoven's formula. The cyanide of silver converts the film into a bluish colour, and might also transform the yellow stain in the same manner.

JACK AND I IN NORWAY.

IX.—NEDRE VASENDEN—FORDE—LANGELAND—SANDE.

THE Inn at Nedre Vasenden is spoken of in questionable terms by Baedeker as to comfort, general providing, and high charges. As far as our experience goes, we can give a direct denial to this statement, for we had good food, comfortable quarters, and the people were more than ordinarily polite; in fact, we had a good time there. Such a representation, however, tells against the house, for as parties came up we could hear the English asides, as they stayed to change their horses: "No, don't stay here." "It isn't good." "You remember what the guide said about it." "Neither comfortable nor cheap." And then they clear out without breaking their fast, preferring to wait till they come to the next station. All we can say in defence of this house is that things must be vastly changed since the derogatory lines were published, or the writer of them expected more than the case warranted. Do not have any fear of putting up at Nedre Vasenden Inn. Should you arrive there of an evening and wish to halt for the night, I warrant you will be comfortable.

This is a delightful spot for photography. The village lies at the lower end of the lake, which curves round, dotted over with boathouses and boats, and as the carriage-way runs close along the side of the lake, which is rich in overhanging foliage, almost any effect could be produced when we waited for the proper light. We had boats rowed out into the lake to break in on the sheet of water, and thus help to make up our foregrounds. We were very successful here.

Here a rustic wooden bridge across the outlet of the lake divides the village. The flow from the lake pursues its course under the bridge in the form of a river rushing down between the mountains. On some islets in the midst of this stream we came upon a group of wooden mills of the same class as have been previously noted, all built side by side, and working away with no end of fuss. We got a negative of them.

When we had finished our exposures at this place, and before

leaving, we asked the young women of the station if they would oblige us by doing up their hair and putting on their headdress (which was peculiar), and let us make a group of them as they parted with us.

The way these girls do up their hair and the caps they wear, to say the least of it, is very remarkable. The hair is dressed and fixed upon the crown of the head, looking like a monster spinning-top turned upside down, the point standing up in the air. Then they have a black silk bag or cap with which they cover this tower, which of course is broad at the bottom and rises to a point at the top. Some six (all the female population the station could boast) willingly donned their best things and in full war paint came out to be photographed. Since coming home I sent them some copies, so, should you happen to pass that way you will likely see them.

The road from Nedre Vasenden was full of interest. We stopped on the brow of the hill when leaving and took a picture of the village from the height, it was so tempting. Right on to Forde (this is the second place of this name, as previously noted) was verdant and pleasant, with waterfalls and rivers to enliven the way. We stayed at Forde to receive and dispatch telegrams and have our lunch at the hotel, which was a well-appointed house with first-rate service. The village itself was remarkably like an English one. We continued our journey to Langeland—a very rough road—and when we reached that place it looked far from inviting. Our driver said he would take us right on to Sande if we wished—and we wished.

The road improved as we proceeded, terminating in a valley, rich in lakes and trees, houses and bridges, and in their midst the ever-present church, and here was the village of Sande. We got in on the Saturday, and resolved to remain in this place over the Sunday.

Here at Sande we had fallen on a hotel comfortable as a home. The waitresses (a native of this place and relation of the landlord) had just returned from America, where she had been residing for some years. She spoke English fluently, hence our conversation was easy and flowing, and for the time being Jack ceased to construct sentences from the Norwegian vocabulary, which he stuck to through thick and thin closer than a brother.

There is a peculiar decorative effect on the walls of the rooms in many places here which is worthy of notice. The walls themselves are painted a neutral grey tint or cream, and over this tint are trained vinous plants, which trail all over the walls right up to the roof. These plants grow out of small pots ranged along the floor close to the wall. It was new to us and very pretty; it looked like a pattern without a set design, and the whole effect was artistic, for the tracings were thin and lacy, and the leaves were never thrown in clumps. The only drawback that I saw to it was the tendency it would have to keep the room damp.

We again met our American friends here. Thomson was full of a peasant marriage party he had just seen, which he described to me much as follows:—"I guess it was about the most premature exhibition that you ever saw since the flood. There were four boats came sailing down the fjord and landed at the quay—men and women—and the blooming bride, like a queen, wore an immense crown upon her head. Every woman carried her own little trunk—you know the sort of thing—and they had no sooner landed, sir, than each on her own account hurried away to any bit of broken wall or other shelter about, and here in all haste began taking off their outer garments and decking themselves in the finery which they had brought with them in their boxes. This performance took place in the open, mind you, and they put their every-day things into the boxes, leaving them there till they returned again. Then they all gathered together in a crowd, smiling and bright. It was a picture, lad, I can tell you. I was wishing I had had you there with your machine."

During the night I was roused out of sleep by the noise of stolecarries and carriages arriving from Vadhem, the port some eleven miles further on. It was about three o'clock in the morning. I got up and had a look out of the window, and saw a lot of people had come, both ladies and gentlemen. I went to bed speculating on the goodly company we would have for dinner on the Sunday, but by the time we had got down to breakfast they had all gone again except two young Englishmen.

These young fellows were in a rather troubled state of mind, which they ventilated to us during breakfast. It seemed that they had come on to Sande to have a good day's fishing, having heard that the proprietor of the hotel held fishing rights on three lakes quite near, which was true, but it turned out that he would not allow any one to fish on the Sunday, and so their prospect of pleasure was knocked on the head. They had arranged to go on after breakfast, but they were rather in a fix about their stolecarries also. They found out after arriving here that the man who had brought them had swindled them; he looked like a sharper, and talked Yankee. He had accosted the young fellows at Vadhem, stated that he was going their way—had to take the conveyance and horse into the country, at any rate—and that he would take them much cheaper than the regular conveyance; he was going as far as Ardal, and would wait where they stayed, and take them right along all the way. Being strangers the young fellows looked upon this offer as a good chance, and accepted it. They were to pay at every stopping station, so had settled up to Sande. Then it turned up in conversation that they had paid on demand ten shillings for an eleven miles drive, the Government arrangement being four shillings only for two for this distance. Of course, when they found this out, they would not have the man any more, but both

were rather nervous about tackling him; they were but boys, and he looked a tearing, swearing personage, and I did not wonder at their hesitancy. At length they applied to the landlord, and he soon made short work of the matter. Oh, how that fellow swore as he turned his horse's head towards Vadiem again!

This is a trick that is regularly played at some of the busier landing stages. An offer of private conveyance going your way—carry you cheap. When they get the unwary trapped they can charge what they like, being bound by no law or regulation. Beware of such.

The church here is open but once in three Sundays, the minister travelling into more distant villages on the two Sundays between, that being three congregations that he has under his charge. The Sunday we were in Sande happened to be the one that the pastor officiated there. This gave us an opportunity of seeing the service.

The members of the congregation are scattered all over the countryside for miles, and this is the grand occasion on which they meet and converse with each other. All this morning we could see little groups straggling into the village, dressed in their best, then coming to a focus in knots around the church, evidently retailing the interesting items of their quiet lives since last they met. The landlord was saying that most of the love-making was done at these Sunday gatherings—a good beginning for a married life.

The church was built of a light wood, with a red-tiled roof. During service all the men sat down one side of the church, and the women the other—just like a Quakers' meeting. Nails were fixed into the wall along the side at which the men sat; on these they hung their hats and caps.

The service itself seemed to me a blending of Catholic and Protestant. There was an altar with a statue of the Virgin Mary over it, this surmounted by a cross. In front of the altar was a raised platform, shaped half circle and railed round. This space was about twelve feet deep, and here the minister walks about during the time that he is officiating and preaching. The minister is robed in a white gown and wears a large Queen Mary ruff round his neck. His exhortation did not last more than twenty minutes. The singing was very uncultivated and decidedly unpleasant. After the discourse the members came forward to be blessed by the laying on of hands. The husbands and wives came first and knelt down round the railing that enclosed the platform. The pastor then put his hands on the heads of husband and wife and blessed them in a short prayer. Then he repeated this with the next couple, and going on until he had completed the circle in twos and twos. When they retired to their seats another company, equal to the filling of the space, came forward, and so on till all the married people were done. Then came the widows and maidens, and last, the widowers and young men. This part of the service would occupy half an hour.

During the service the congregation are evidently accustomed to take things free and easy, for if any of them felt weary sitting they just stood up and looked about them till they had rested themselves, and then they sat down again. It struck us as very amusing to see the people pop up every here and there in the middle of the sermon, and after their eyes had travelled all over the place, as if in search of some one, to quietly sit down again. It's a way they have; I suppose their fathers did it that way. There were five children christened on that Sunday.

On Sunday evening Jack amused himself with his binocular, taking considerable interest in the burly parson, who stayed in a neat little cottage just over the river from the hotel. He was sitting in a garden plot in front in his shirt sleeves, smoking the pipe of peace. Next morning we found him toiling away on his little farm. It evidently took the pasture as well as the pastorate to square his living.

Our American friends drove on to Vadhem on Sunday night, we promising to meet them there on the morrow, as we intended to take some negatives on Monday before going forward.

MARK OURE.

TIME SIGNALS BY THE MAGNESIUM LIGHT.

HAVING recently seen a magnesium flash light used for instantaneous photography, it occurred to me that the intense light produced could be utilised to advantage for distributing standard time signals by night. I decided to test the principle in a practical manner, and have obtained some very satisfactory results. The ordinary flash lamp, as made for photographic purposes, is an alcohol lamp giving a large flame through which a charge of magnesium powder is blown by means of a rubber bulb held in the hand. On pressing the bulb the magnesium is instantly ignited by being brought in contact with the alcohol flame. A lamp of this kind was fastened to a suitable frame, to which was attached a common telegraph sounder. A heavy weight was suspended over the bulb of the flash lamp in such a manner that it could be instantly released by the action of the sounder, thus depressing the bulb and firing the magnesium. The apparatus was connected with the signal circuit of the standard clock, and a series of experiments was made. By previous arrangement the signals were observed by Mr. H. H. Clayton, of the Blue Hill Observatory, at a distance of twelve miles, and were seen with great distinctness. Rough observations showed that the time lost in the action of the firing mechanism was less than 0.4s. This error was nearly constant, and can be rendered practically inappreciable by properly constructed apparatus, specially designed for the purpose. The

flash light would have the advantage of being visible to the unaided eye at a much greater distance than a time ball.

Being necessarily used in the evening, it would be seen by many whose only leisure time is after working hours. A flash signal fired from a hill or from the top of a high building would be visible in all directions for many miles. The cost of the apparatus is very small when compared with that of the time ball. I think that a system based on the principle which I have described will recommend itself to those interested in time-service matters as cheap and effective.

WILLARD P. GERRISH, *Harvard College Observatory.*

THROUGH JAPAN WITH A CAMERA.

CHAPTER IX.—SENDAI—MATSUMA—THE JAPANESE RACE.

ON our return the second time, we were informed that "a lodging had been prepared for us," and were taken, on the morning after our arrival, by a deputation from the local government board, to the best tea-house of the town.

From what has already been said of the tea-houses, it will be understood of those which the Japanese would describe as "number one houses," that they are much more pleasant places of residence than hotels; but it is not customary—in fact, I believe it is strictly illegal—to permit travellers to reside at the former places; that is to say, to stay overnight. They are only intended as places of rest and amusement for the daytime. The local authorities have the power, however, of making an exception in the case of those who are on public business. So in Sendai we found ourselves in what was altogether the most comfortable and convenient place of residence that we had been in since we had started on our journey, especially as we had the whole house, which was very large, practically to ourselves, any guests who came in the daytime being, whilst we were there, entertained in a sort of offshoot from the main house, and there being no visitors in the evening.

Two young ladies of the establishment were deputed to attend on us. These were the adopted daughters of the owner of the house. To be childless is considered in Japan the greatest misfortune, and those who have no children of their own almost always adopt one or more of the children of their friends who may happen to be poor, or to have a very large family.

O Takisan (or Miss Bamboo) and Okikusan (or Miss Chrysanthemum) were the names of our especial guardians. They were both full of fun and frolic, and entertained us most royally. They had a number of tricks and games that they showed us. Okikusan, who was only twelve years—by Japanese reckoning, which means eleven years by our reckoning—could juggle with an apple, a two-sen piece, and a piece of paper, keeping them all going in the air at the same time. Both could construct the most marvellous forms out of paper. The frog that they made was, in particular, so remarkable a work of art, that I wish I had kept him. There was a great folding and twisting of paper, which appeared at last to be reduced to a formless mass, but a sudden puff of air from the mouth into a hole that had been left somewhere distended it, and, lo! there was a frog standing on its four legs, with its head so impudently cocked up, that one expected it to jump from the table. But the crowning accomplishment of both young ladies was that they could stand on their heads. This performance they went through with evident pride; first, it is necessary to mention, arranging their garments, so that they took very nearly the form of the nether garments worn by men in Europe. They were very anxious that I should emulate this performance. I am generally loth to refuse anything to the fair sex, especially when represented by young and pretty girls, for all of whom I have a tender feeling; but, really, one must draw the line somewhere, and, at my time of life, to stand on my head for the edification of two little Japanese girls—well! Besides which, I can't stand on my head if I try ever so hard, and, if I did try, I am not going to confess the same to English readers.

Our business was soon done in Sendai, and we made our way one day to a place about twelve miles off, called Matsuma. It is on the seashore, and is one of the most beautiful spots that I have seen in Japan. A large bay is dotted over with innumerable little islands of rocks with what looks like a tuft of pine trees growing on the top of each. The stone constituting the islands is soft, and the water has undermined it into all sorts of fantastic shapes and forms. I had taken my camera with me, but just as I was about to set it up, the sky, which had been clear, suddenly overclouded, and we had scarcely time to run for shelter when a thunderstorm began, which made all photography out of the question for that day.

As we made our way home we observed a curious custom of the country. In front of every house (it was now fair again) was erected a bamboo tree, decorated with strips of brightly-coloured paper and garments of the same material, very like what we find in children's crackers at home. This is, it appears, an ancient custom which is observed yearly on a certain day. The girls of the family make the paper garments which decorate the tree, and, in return, are gifted with the capacity to sew neatly. The boys write mottoes on the strips of paper, and thereby secure a good handwriting. It seems a pity that this simple means of securing a decent "fist" was not known to the writer's parents some twenty-five years ago. It would have saved a world of subsequent trouble to contributors and others.

The day was, it appeared, a sort of festival, and, as we got towards our lodgings, when it was darkening, the houses were all decorated with coloured lanterns and other devices. In front of our own tea-house there was hung up a huge strip of transparent paper lighted with candles in the inside. As was to have been expected, it caught fire, causing no little excitement.

Our tea-house looked out on a sort of square park surrounded with shops and booths, which were all decorated with strange devices, for the most part of paper, with candles burning in the inside of them, and the little Miss Chrysanthemum, who had become quite tyrannical by this time, insisted on being carried pick-a-back all about the place to see the sights. She apparently looked on the writer as a sort of good-natured barbarian, to be treated with some consideration so long as he behaved well; but to be kept strictly under control.

In the evening a third young lady, O Minesan (or Miss Mountain-top) appeared on the scene, and the good lady of the house herself favouring us with her presence in our sitting room, there were games of hide-and-seek and blind-man's-buff, and other childish follies that I had not indulged in for many a year. The great old house rang with peals of merry laughter till, I think, the small hours of the morning; the old lady, the meantime, continually smiling with good nature enough to make her look pleasant, spite of her blackened teeth. The custom of blackening the teeth of women at the time of marriage has, by the way, almost entirely gone out in Tokio, the capital, but is still practised in the country.

There is a great misconception on the part of many foreigners as to the object of the blackening of the teeth. I have seen it repeatedly stated that the Japanese blackened the teeth and erased the eyebrows of the women at marriage so as to disfigure them. A strange idea, surely, that a man should wish to disfigure the woman he takes for his wife, even supposing the woman would submit to it; but the truth is that the two practices alluded to—the blackening of the teeth and the erasure of the eyebrows (false ones being painted in higher up)—was supposed to add to the charms of a woman. This is conclusively proved by the fact that, before foreign customs were adopted, the most fashionable courtesans in Tokio had their teeth and eyebrows treated in a similar manner; but, however this may be, the blackened teeth are, to the eye of an European, a frightful disfigurement, and the custom of keeping the natural colour of the teeth is a foreign importation that few will regret.

I made a few exposures on the young ladies, and am very sorry indeed that one of them resulted in failure, as I intended to use it to illustrate some remarks.

When an European first comes to Japan, he can see but little distinction between one individual and another. The differences between the different Japanese is lost in the great difference between them and Europeans; but after a little time he begins to see that the Japanese consist of two distinct and clearly-marked races. There is the aristocratic and the plebeian type. There is a real and actual class difference, so that, whereas in England, if a thousand children of the poorer classes and a thousand of the upper classes were taken at birth, and were similarly educated in every way, it is doubtful whether the two sets would show any marked difference, and it is certain that of the majority of individuals it would be impossible to say from which class they had sprung; in Japan, if the same had been done before the feudal system was abolished, the difference would have been clearly noticeable in every, or nearly every, individual case.

It is a question, and one which it would be most interesting to have solved, whether these two classes represent two originally different races—a conquering (and therefore, presumably, superior) and a conquered race, or whether the difference has grown up by degrees through centuries, during which the habits, food, surroundings, &c.—in fact, the environment—of the one class was totally different from that of the other, and in which—so strictly was feudalism enforced—the two classes were kept totally separate, to pair from the one to the other being impossible.

Students of Darwin will perceive in the fact that the distinction is not perceptible at an early age, some evidence in favour of the latter supposition. On the other hand, however, it may be argued that all babies are precisely like one another: they are all like so many dabs of putty. (Mothers, please take note.)

O Takisan (or, as I have called her, Miss Bamboo) had a typically aristocratic face, and it was when photographing her in profile that I, for the first time, understood why so many maintain that the Japanese aristocratic class is Jewish in its origin ("lost tribes," of course, some hold). Leaving the head-dress out of the question, O Takisan's profile might have been that of a Jewish maiden of quite pronounced national type. There was the same delicate aquiline nose, and slightly pouting lips; in fact, a Jewish face. The other class much more closely approximates to that of the Negro—there is a low squat nose, and very thick lips of a coarse nature.

This question is a very interesting one, and is one that might probably be elucidated to a certain extent by composite photography. I am glad, therefore, to hear that Professor Hitecock, of the Smithsonian Institute, whom I have already mentioned as at present in Japan, contemplates attempting some work of the kind. It will soon be too late to do it, as with the overthrow of the feudal system, the barrier between the classes was broken down, and the distinction between them will, doubtless, soon disappear.

At Sendai the good people entertained us in "European style." Those

who have read the description of the Japanese style of entertainment will probably think with me that, as an entertainment, the English dinner is flat, stale, and unprofitable compared with it; but I must say that after three weeks on Japanese food, I enjoyed the actual feed immensely, and ate so much that I am surprised that I was not very ill afterwards.

W. K. BURTON.

Foreign Notes and News.

PHOTOGRAPHERS in their travels sometimes run short of magnesium. Messrs. Rossignol & Fleury-Hermagis recommend the following mixture of chemicals, as calculated, on account of the photogenic power arising from its combustion, to help them out of their difficulties in this respect:

Flower of sulphur	40 parts.
Red lead	50 "
Sulphide of antimony	70 "
Nitrate of potash (powdered)	50 "

These substances are to be intimately on a large sheet of paper, or better, in a glass mortar, after having been previously dried in the sun. Ten to thirty grammes of the mixture suffice to illuminate the interior of a crypt, a cavern, &c. It may be ignited by an ordinary match, or, if it has got at all damp, by a piece of glowing charcoal.

ACCORDING to Dr. Zerger, of Prague, photographs of the sun taken on orthochromatic plates, furnish a means of predicting, by more than twenty-four hours, the approach of tempests, hurricanes, earthquakes, &c., a knowledge of whose advent would be obviously of much value to the tourist. These photographs display the appearance of more or less elliptical rings surrounding the solar disc, which, when they grow larger in diameter, announce the approach of a hurricane or other atmospheric disturbance towards the point of observation.

APPROPOS of paraphenyldiamin, Professor Eder, of Vienna, writes:—"According to the experiments which I have been conducting in conjunction with Herr Ritter von Reisinger, it appears that paraphenyldiamin ($C_6 \times 1_4 [H N_2]$), which was manufactured by Dr. Schmeider, in Görlitz, acts as a good developer for bromide of silver gelatine plates. It gives about the same degree of sensitiveness (on testing with Warnerke's sensitometer) as pyro or hydroquinone developers. We employed a mixture of 1 part of hydrochloric and 1 part of a solution of paraphenyldiamin, dissolved in 50 parts of water, and 1-2 vols. of a potash solution (1:10). The development took place with regularity, the colour of the silver precipitate being grey, and the negative of much delicacy. Sulphite of soda keeps the solution colourless for a long time, but restrains the development of the image in a high degree."

DR. CARL FENA gives the following formulæ for a pyrocatechin developer

A.	
Sulphite of soda	100 grammes.
Distilled water	400 "
B.	
Carbonate of soda	100 grammes.
Water	400 "

Take 30 c.cm. of A and mix with 60 c.cm. of B, and add 1 gramme of pyrocatechin. This developer appears to act much more energetically than a similar developer with hydroquinone.

A FRENCH Amateur has tried the following formulæ for a citric acid developer with success:

A.	
Citric acid	25 grammes.
Water	700 c.c.
Ammonia (sp. gr. 0.81)	1 part.
B.	
Ferrous sulphate	1 part.
Water	3 parts.
C.	
Sodium chloride	1 part.
Water	30 parts.

Mix 15 parts of A, 5 of B, and 1 of C. It is probably the cheapest developer that can be used for gelatino-bromide, and is said by its discoverer to give excellent results. Perhaps!

HEAR SALYER recommends the following method of testing citric acid for the presence of tartaric acid. It consists in simply adding to the suspected solution one drop of yellow chromate of potash. If the citric acid be pure, the slight yellow colouration will remain unaltered for several days, even after the addition of some drops of sulphuric acid; if tartaric acid be present, the yellow chromate is converted into a violet salt of chromic oxide. Herr Salyer adds that even half per cent. of tartaric may

be detected in this manner on the solution being allowed to stand for some hours.

THE well-known firm of E. Jaffé & A. Albert, of Vienna, has been awarded the gold medal for photographic exhibits, apparatus, &c., at the Budapest Industrial Exhibition.

IN Germany a new patent has been recently granted to Dr. M. Andresen for the employment of the diamido-naphthalin-sulphurous acids and the amido-naphtho-sulphurous acids as developers for photographic purposes.

THE *Photographisches Wochen Blatt* draws attention to the fact that after toning prints, especially in a gold bath, the action continues while they are being washed, and that this especially takes place where two prints lie one upon the other. Our contemporary recommends the employment of ten per cent. solution of salt, by which the toning solutions are so rapidly removed that the action is brought to an end at once.

Our Editorial Table.

PICTURE MAKING BY PHOTOGRAPHY.

By H. P. ROBINSON. Second Edition, Revised. London: Hazell, Watson, & Viney, Limited, 1, Creed Lane, E.C.

WRITING in another place and at another time *apropos* of the first edition (1884) of *Picture Making by Photography*, we remarked that the reason we attach importance to the teachings of Mr. Robinson is that he possesses a trinity of qualifications: he is a good technical, practical photographer, and in virtue of this he takes, technically, perfect photographs; he is an artist, and therefore his photographs are works of art—by which we mean fine art, in contradistinction to technical art; lastly, that he is not only well conversant with the canons of art, but he is a facile writer and master of the art of conveying his ideas to others in a manner capable of being understood.

In perusing this new edition, we notice revisions of and improvements upon the former one. *Inter alia*, we observe with satisfaction two full-page reductions of, perhaps, as charming works as have ever emanated from Mr. Robinson, viz., his *A Merry Tale* and *Wayside Gossip*. Either of these are as natural and good as if a photographic spy with a detective camera had been dodging the party from behind a tree or a rock and had pressed the trigger at the fitting moment, so entirely free are the components of the group from that hateful idea of being posed for a photograph. But the art of concealing art has here been carried to its highest development, and we do not mind cribbing a little bit from Mr. Robinson's 146 pages to throw a little light upon his method of making a picture. As will be seen, the picture in question is *A Merry Tale*, and the incident is extracted from the chapter entitled "The Genesis of a Picture."

Sometimes incidents you meet with in the streets, or in country walks, will suggest subjects—not necessarily the actual incident one sees, but something that may be worked into some other scene, with perhaps many alterations. Sometimes a fine pose may be seen, or a lovely bit of light and shade; sometimes an expression or a quaint costume; all these things should be noted for future use. No suggestive bit should be allowed to escape; all should be sketched or noted. It is good practice also to try to analyse why the pose is beautiful, or the light and shade effective. This a knowledge of the rules of light and shade and composition will enable you to do, and to do this easily the student will find an added pleasure to his life—another feather to the wing of his artistic flight.

We will now take a picture that has been really produced by photography, and see how it was conceived and finished. To analyse and dissect a picture in a cold-blooded way, as I am going to do now, is to rob that picture of any poetry it may contain, and leave nothing but a mechanical interest; but I know no better means of conveying the information; I will, therefore, take one of my own—that one I have called *A Merry Tale* will be suitable for the purpose. The frontispiece is a reduction of this picture, and will assist the reader in understanding what follows.

In the drawing-room of a country house in North Wales five young ladies in evening costume were amusing themselves after dinner. One of them was relating some funny circumstance to the others, who arranged themselves in a picturesque group round the story-teller. Here was the germ of the picture. A few seconds sufficed to make a sketch of

the composition. The illustration is a reproduction of the jotting in my note-book, and, as I have already said, would enforce the practice of making rough sketches of composition; and light and shade is very useful, especially if accompanied by a few descriptive notes. It teaches the student how to observe, if it does no other good. Correct drawing is by no means necessary; the "effect" is what should be noted. To return to the picture. By an easy transition the mind easily changed the young ladies into peasant girls, and suggested suitable surroundings. A sketch was made of the arrangement, and the dress for each figure decided on. In selecting the costumes, the light and shade of the group, and its relation to the landscape, were not forgotten, neither were the accessories—the baskets, jug, and stick. The colours were taken into account only as to how they would translate into black and white.

It was arranged that the group should form part of our work for the next day; but, as often happens in the mountainous districts of Wales, man proposes and the weather imposes: the morning opened with a deluge of rain, which continued more or less for several days. Those days were not wasted, for young ladies nowadays cannot only play tennis, but some of them can shoot and throw the fly, to say nothing of ratting and ferreting! At last the storms were over, and the sun shone again, but with a great deal more wind than a photographer thinks pleasant. However, we determined that we would have some pictures, good or bad, that morning. We were getting hungry for work, and a conscientious photographer is as anxious to make a good bag as a sportsman, but a photographer's desire for picture making is nothing to that of a set of really enthusiastic models. Mine, I know, go into the business with the greatest energy. Off we started to a quiet lane about a mile away. The photograph conveys no idea of the picturesque effect of the five girls in their humble but brilliantly-coloured garments. The effect of colours under the green hedges and through the fields was quite beautiful. The choruses sung on the way had, perhaps, nothing to do with photography, but the foxgloves and other wild flowers the singers gathered came in very useful in the picture. Arrived at the selected spot, the camera was unpacked, and the models placed approximately in their proper places, interfering branches cut away, and everything got ready, so that the last moments might be devoted to the quite final touches, expressions, and other little things. The sun shone a cold steely blue, and the wind was so troublesome that we had some thoughts of giving it up after all; but we decided we had taken too much trouble to go home without spoiling, at least, one plate.

Now for the arrangement of the group. The girl to the left was sitting up at first, as will be seen in the sketch, but being a young hand at the business, she could not control herself, and, enjoying the fun, threw herself back on the bank screaming with laughter. This was a happy accident, which much improved the composition, and was seized immediately. She was at once shouted to to keep her place, which, being an easy one, required little further thought on the part of the photographer, who could now turn his attention to the other figures. The seated figure, the one in the straw hat, was a steady old stager with plenty of experience and no nerves; she required but a moment's attention. The next figure, always dramatic in pose, and with a charming expression, is, perhaps, in consequence of her other good qualities, rather shaky as a sitter. She required a rest of some kind. The stick was useful here, and was of immense value in the composition. A bit of straight line to contrast a number of curves is always effective. This settled the three figures that were easiest to keep still. The standing pose being by far the most difficult to keep—for a standing figure without a rest often sways like a pendulum—was left until last. The figure telling the story was now settled; the pose came easy, the model being an admirable story-teller, and thoroughly up to her business; but it was necessary to give all possible effect to the hand, for the hand, if well placed, would do more towards showing the intention of the picture than anything else in it. It, in a way, leads the chorus of expressions; it emphasises the situation; it makes you feel the girl is speaking. It was so arranged that, to make it more conspicuous, it should appear partly in sunlight and partly in shadow, and every leaf or twig that came behind it was hurriedly removed. The standing figure, who could not be expected to keep the pose for above a minute or two, was placed last. The jug, basket, and foxgloves, which form the keynote of the composition in the foreground, had been previously arranged, and all was ready. But a last glance from the camera showed the photographer that the tree was exactly over the head of the standing figure, and cut the composition into two parts. This would never do. But instead of moving the model the camera was moved. This corrected the error to some extent. It would have been better to have moved it a little further, but it was feared the other tree would interfere with the story-teller. A few last words—at the special request of the models I use fictitious names—"Now, girls, let-

this be our best picture. Mabel, scream; Edith, a steady interest in it only for you; Flo, your happiest laugh; Mary, be sure you don't move your hand, or all the good expressions will go for nothing; Bee, I will say nothing to you, but leave you to fate. Steady! Done!" and two seconds' exposure settled the matter. I scarcely expected a successful result, the thing was so difficult; but as the wind was blowing almost a gale I did not care to try another plate. As it happened, I found, when I developed the plate a fortnight afterwards, I had got a good negative. The sky was white and blank; but the use of a second negative, delicate and not too obtrusively printed, soon put this matter to rights.

This seems a long story to tell, but the picture was exposed in under six minutes from the time the models first took their places. This quickness is one of the secrets of success, but when your picture is to include figures it should not have the appearance of hurry, for "hurry hinders haste," and, besides, has the effect of hurrying your models: it should be the result of a perfect knowledge of what you want to do. A model should never be kept waiting longer than is absolutely necessary. It is better to give up little things rather than to lose a fine effect.

The lesson to be drawn from this is the vital importance of seizing such ideas as present themselves, and boiling them down or summing them up, making careful notes and taking them (as a Scottish judge would say) *ad arandum*, and finally out of this digested material making the picture.

Starting the work with chapters on "Gelatine Plates and their Uses," and "Our Tools," our author in the former speaks of their value in permitting photographers to introduce figures; and in Chapter XI. ("Figures in Landscape") he reiterates the advantages of this class of introduction. That figures, as he says, "may often be made to tell a story, or illustrate a poem or poetic thought," is an undoubted fact; but we rather wish that he had devoted a chapter to warning photographers against the introduction of figures in season and out of season, for this is a weakness to which many photographers are terribly addicted, and by which many otherwise good landscapes are spoilt. Is it a river? Then, of course, we must have the inevitable fisherman with his rod and basket. A country stile? Then must Joan and Darby be posed there, one on each side, and in all that stiffness engendered by the all-prevailing thought that they are being "took." Even a lonely shore can't be let alone, but some Dulcinea must be introduced in town-made habiliments of latest fashion to mar the loneliness.

In the next edition, which is sure to be called for, we conjure our author to devote a chapter to the abomination of commonplace figures being stuck in, here, there, and everywhere, without "rhyme or reason," to destroy the beauty of landscape nature. "Did you ever see a more beautiful landscape?" asked an artist of us as he stood before a photograph by a young artist in the Newcastle Exhibition, with his thumb broadened upon a certain portion of it. Its beauty was acquiesced in. "But see now," he said, withdrawing his thumb, which had hidden two figures prominently placed in the picture, "it's beauty is all gone; these figures have spoilt it." Now figures are all right enough, and they may be made to enhance the value of a picture, but they must be introduced with exceptional judgment in order to this. They are like sharp edge tools, capable of much evil as well as of much good. Therefore, Mr. Author, in your next edition, please devote a special chapter to the misuse of figures in landscapes. Still, the chapter on figures is valuable and suggestive.

The work contains twenty-one chapters, and takes us through the rudiments of composition, light and shade, models, subjects, animals, the sky, and the other points to be noted when making "pictures by photography." They are written in a terse, vigorous, and healthy style, and now that the technics of photography are fairly well understood, cannot fail to raise the mind of the careful reader above merely clean and faultless negatives.

We are pleased to see that a chapter has been devoted to *Naturalistic Photography*, the "new heresy," if heresy it be worthy of being called. He naturally alludes to the writings of Dr. Emerson, with which he is not in accord. He says:—

In imitating the impressionists, Dr. Emerson has to give up the quality for which photography is distinct from all other means of art—its great facility for giving definition. It is recognised by all artists that each art should take advantage of those features which are peculiarly distinctive in its practice; oil painting has richness, transparency, and depth; water colours, luminosity and clearness; photography has something of

all these qualities, but its most prominent feature is that of definition; yet Dr. Emerson would have us give up this great feature, so that we may imitate the effects of a totally different method of artistic expression. Dr. Emerson has thought fit to write of Mr. Ruskin as a "spasmodic elegant of literature," and a "splendidly false critic," therefore I cannot expect him to treat any word of the author of *Modern Painters* with respect; but the rest of the world still recognise in Mr. Ruskin the greatest writer on art that ever lived, and in *The Two Paths* he lays it down as one of the main principles of all work "that whatever the material you choose to work with, your art is base if it does not bring out the distinctive qualities of that material." And he says further that "the reason of this law is that if you don't want the qualities of the substance you use, you ought to use some other substance: it can be only affectation and desire to display your skill that lead you to employ a refractory substance, and therefore your art will be all base." Now definition is the distinctive quality of photography, and it follows that according to the dictum of our greatest writer on art, naturalistic photography which omits definition is base art. No wonder that Dr. Emerson should denounce Mr. Ruskin as a splendidly false critic!

Naturalists pretend to represent what they see, but healthy human eyes never saw any part of a scene out of focus. The moment they are turned from the object on which they were fixed to find a part out of focus that part instantly becomes in focus. The proof of this simple statement—and any pair of eyes can prove it for themselves—ought to bring conviction of the unnaturalness of naturalism. It is quite true that the planes in nature become indistinct as they recede; this is not because they go out of focus, but is due to the intervention of atmosphere. This effect can be represented in photography without putting the lens out of focus, which is a poor artifice for the representation of atmosphere; nature may have been all wrong when she made what has been thought the most delicate and beautiful organisation in man; but we know what the eye is, and we must take it such as it is, and everybody who has one can tell how much he can see by simple experiment, and that is what should be represented. But I must guard myself against being misunderstood. What the physical eye sees does not mean that the eye cannot be trained to see by the mind. It has been said that the eye only sees about five per cent. of what is before it; this is true in a double sense; but physically the eye only sees an angle of five degrees at one time, but changes so quickly that it practically sees the whole of a scene at once.

The book is well got up, and contains many small illustrations. Price 2s. 6d.

PATENTS COMPLETED.

IMPROVEMENTS IN OR PERTAINING TO PHOTOGRAPHIC CAMERAS.

No. 939.—ALFRED SMITH, 5, Cambridge Lodge-villas, Cambridge Heath, Middlesex.—*July 20, 1889.*

THE object of my invention is to fit photographic cameras, especially those known as "detective" or hand cameras, in such a manner that a large number of sensitive plates may be exposed in succession without the necessity of opening the cameras.

In carrying out my invention, I construct a box or case of any suitable form, preferably rectangular, in one end of which, and in the lower part thereof, the lens is fitted, with suitable shutters. View finders may also be fitted in the lid of the box.

According to one form of my invention, a plate is fitted vertically in and against side of the case, and preferably about half the length of the same, which plates can be caused to move along the sides by racks and pinions, the pinions being operated from the outside of the case. In these plates are formed a number of corresponding vertical grooves. A horizontal partition is fitted in the case in such a position as to divide the case into two somewhat equal parts, and transversely in this partition is made a long slot, about midway in the length of the case, or the horizontal partition may terminate in this position. The sensitive plates are placed separately in the grooves of the two side plates above the horizontal partition, their lower edges resting on the same, and each plate must be backed by some opaque material, for which purpose I preferably place each plate in an open-faced holder, each holder being placed in the grooves of the side plates. When it is desired to place one of the sensitive plates in position to receive and be acted upon by the light

through the lens, the two side plates are moved backwards until the hindmost plate or its holder arrives at the slot in or at the end of the partition, when it slides downwards in the grooves by gravitation until it is checked and held in the proper position behind the lens, with its sensitive surface presented thereto, and when the desired exposure can be given, after which the two side plates are again moved backward until the next plate or its holder slides downwards in its grooves into position, until all the plates have been utilised. As each plate is backed by an opaque material, no damage is done to those plates which have before been exposed.

According to another form of my invention, each side plate is divided horizontally into two parts, and separately fitted above and below the horizontal partition, and the pinion is mounted between the same and caused to gear into racks fitted to each part. The sensitive plates are placed, as aforesaid, between the two upper side plates above the horizontal partition. When it is desired to place one of the sensitive plates in position, the upper side plates are moved forwards and the lower side plates backwards until the front plate and its holder can slide downwards over the end of the horizontal partition or through the slot therein into position as aforesaid. A stop may be fitted in the lid of the box to ensure that the plates shall so slide downwards when required.

IMPROVEMENTS IN PHOTOGRAPHIC NEGATIVES AND SENSITISED PLATES FOR USE IN PHOTO-ILLUSTRATIVE PROCESSES.

No. 9921. HERBERT DEVERIL and WILLIAM GALLAGHER, Sydney, New South Wales.—July 20, 1889.

This invention relates to improvements in photographic unvarnished negatives and in photographic sensitised plates, by means of which the pictures obtained upon them may be printed in greasy or fatty ink on the ordinary material and transferred to stone, metals, wood, glass, porcelain, or other substances for printing, etching, or engraving, or other illustrative or ornamental purposes, and revealed thereon in minutest detail and with half tones and all degree of shadow clearly defined.

This improvement in photographic negatives and sensitised plates for use in photo-illustrative processes, is comprehended in the obtaining in the negative from which the picture is printed on the usual and ordinary transferring material of non-actinic, opaque, or semi-opaque dots, lines, grains, or suchlike. These dots, lines, &c., may be of a latent character upon sensitised plates, and are developed with the pictures upon such plates after exposure in the camera, or they may be superinduced upon developed unvarnished negatives.

In carrying out this improvement in photographic negatives and sensitised plates for use in photo-illustrative processes, what is for convenience sake termed a "mater" is first prepared. This consists of a sheet of glass or transparent or semi-transparent paper or other suitable substances rendered opaque or non-actinic except in dots, lines, grains, or suchlike, which remain transparent or semi-transparent. This "mater" may be prepared in any convenient manner; for instance, it may be a dry print on thin photographic paper (preferably Rives) obtained from a lithographic stone evenly coated with stiff lithographic ink, or preferably it is an ordinary photographic negative of a drawing, or material, or substance which will give the desired result. Having this "mater" at hand, it is used as desired for converting the "plates" or the "negatives" into suitable means for obtaining the required "transfers."

An ordinary sensitised plate (of gelatino-bromide of silver manufacture), with its face upwards and its back protected with a dark, non-reflecting material, is exposed for a very brief period in an ordinary printing frame under a "mater" (face downwards), to the action of weak white or actinic light, say for from three to twenty seconds, according to the density of the "mater" to the light of an ordinary paraffin candle, and it is then ready for use immediately or at any future time to obtain a picture by exposure in a camera, and which after ordinary development will be seen to consist of a greater or lesser quantity of minute opaque or semi-opaque dots, lines, grains, &c., as are required to produce white dots or grains, &c., in the resulting transfer, and it is printed from upon sensitised transfer paper or material in the ordinary way. Instead of being treated under the "mater" before exposure in the camera, the "plate" may be so treated after exposure in the camera but before development.

An ordinary unvarnished developed negative (having a gelatine film) is immersed in a saturated solution of bichromate of potash for, say, ten to fifteen minutes (the surplus solution blotted off to prevent crystallisation of the salt), and then dried in the dark, when it becomes sensitive to white or actinic light. It is then exposed to strong white light (sunlight) in a similar way to the exposure of the "plates" before described under the "mater," until opaque or semi-opaque dots, grains, &c., appear, such dots, &c., being in fact minute portions of the negative reduced into a resinous substance, which remaining in union with oxide of chromium is insoluble in water. The negative is then washed, and when dry is ready for immediate or any future use in printing a "transfer."

We would have it understood that we do not confine ourselves to the precise manner and the details thereof described of carrying our improvements in photographic negatives and sensitised plates for use in photo-illustrative processes into practical effect so long as the nature of the said invention be retained, but,

Having now particularly described and ascertained the nature of our said invention, and in what manner the same is to be performed, we declare that what we claim is:—1. A sensitised photographic plate having upon it latent dots or marks which during development become and afterwards remain opaque, or semi-opaque, or non-actinic, substantially as herein described and explained. 2. A photographic gelatine negative having upon or within the developed picture superinduced opaque, or semi-opaque, or non-actinic dots or marks, substantially as herein described and explained. 3. A sensitised photographic plate for the obtaining of negatives for photo-illustrative processes, prepared in the ordinary manner and before or after exposure in a camera, by an exposure to light under a "mater" or non-actinic sheet, having transparent or semi-transparent dots or marks, substantially as herein described and explained. 4. A photographic gelatine negative for photo-

illustrative processes, prepared by converting minute portions, or dots, or marks of an ordinary photographic negative into a substance insoluble in water, and preferably by treating such negative with bichromate of potash, and exposing it to light under a "mater" or non-actinic sheet, having transparent or semi-transparent dots or marks, substantially as herein described and explained.

AN IMPROVED PORTABLE PHOTOGRAPHIC CAMERA.

No. 11,300. SAMUEL GEORGE HARRISON-DEARLE, 80, Islington, Liverpool, Lancaster, and THOMAS HENRY ASHCROFT, 8, Marine-terrace, Liscard, Chester.—July 20, 1889.

THE object of our invention is to produce a camera in and by which photographs can be taken or obtained while the camera is carried by the hand or otherwise, and these photographs can be so taken or obtained without the knowledge of any bystander, and this our camera can be constructed very cheaply, and can be arranged to receive and use plates of any desired size.

To carry out this object we form a box or case, preferably of wood, and of the desired shape and size, and the outside of this box can be covered with any material, or be otherwise so treated in any usual manner as preferably to look like an ordinary package or receptacle that is usually carried by a handle on or in the upper part or top thereof, and the side of this box can be opened to allow of access to the interior thereof, and the whole box is or may be so constructed as when closed to be light-tight. In one end of this box is made an aperture, behind which is pivoted or centred on the box or elsewhere a circular or segmental or other shutter, wherein is an aperture corresponding with the aperture in the box, and a spring tongue or catch is fitted which can hold and retain this shutter in position to close the aperture in the box; and when this catch is retired a spring applied to the shutter causes the same rapidly to revolve, during which revolution the aperture in the box is uncovered by the aperture in the shutter, and then closed again by the solid part of the same, and the shutter can be revolved back against the spring from the outside of the box by a button on its pivot or centre, or by other appliance, until the catch can again hold and retain the same. The aperture in the box can be masked by one of the ordinary name labels, or otherwise so fitted on the outside of the box as to be capable of being turned back or removed to unmask the same. Behind the aperture in the box and the shutter is the ordinary or other lens mounted on and connected with another light-tight box or camera, so formed and fitted, and so secured in and to the outer box or camera, as to be capable of being lengthened or shortened as may be desired; and in or at the rear end of this inner box are fitted the usual grooves or guides in and along which the dark slides that contain the sensitive plates can be passed, or the rear end of this box can be otherwise fitted as may be necessary for the particular sensitive appliance or apparatus or device that is to be used, and a screen or screens can be fitted to prevent the light reaching the lens even when the side of the outer box is opened. The outer box can, if desired, be so lengthened at the rear of the inner box as to carry a number of dark slides or other desired articles.

Thus, when the shutter is properly set, and the sensitive plate or other article is duly exposed in the inner box, the catch is retired preferably by a wire or pull passing out at the side of the box or elsewhere to the handle, so that an unobserved pressure by the thumb or finger can so retire the same, and the shutter revolves, giving the desired exposure to the plate or article through the lens, and the photograph is taken.

In order that it may easily be known at what view or thing the lens is directed, two apertures are made in the outer box, one being in the front end thereof, the other in the top thereof, and preferably near the corner of the box, both of which apertures can be masked, as is the aperture for the lens; and inside the box is fitted any usual or other view finder, the glasses and lenses, and reflectors of which are so formed and arranged, and the apparatus is so fitted in the box, that on looking down into the aperture in the top of the box the operator can see the view or thing to which the lens is directed.

Though we preferably use a revolving shutter in this our camera, as is aforesaid, we can obviously also use a drop or any other usual kind of shutter when it is desired so to do.

The claims are as follows:—1. A photographic camera substantially as described herein, with a covering such as shall prevent its outer appearance resembling in any way a photographic camera, preferably taking the shape of a picnic basket covered preferably with American cloth, only exposing to view a portion of wickerwork holding the handle, also composed of wickerwork. 2. A photographic camera with the shutter discharged, and working from the handle of the box containing the camera, necessitating the use of only one hand in making the exposure, that hand being the hand holding the said detective camera, substantially described herein.

AN IMPROVED PROCESS FOR THE TRUE REPRODUCTION OF THE COLOURS OF NATURE IN A COMPOUND PHOTOGRAPHIC PRINT.

No. 13,301. HENRY CHARLES BOND, Highland-road, Bromley, Kent.—July 20, 1889.

MY invention relates to an improved process for the true reproduction of the colours of nature in a compound photographic print, and has for its object the obtaining of the required results by natural means, without the use of the brush or any manual application of pigments, such as crystalline, to the finished prints. In carrying my invention into practice, I take three plate-glass troughs, composed of two thin sides cemented together round the rim and held apart by narrow strips of plate glass of suitable thickness, and fill these with liquids, each of such colour as shall transmit all solar rays, except those forming one of the primary colours.

Thus: The first will be filled with a green solution (preferably chlorophyll in alcohol), which transmits all rays but red; the second with an orange solution (preferably ferric sulphocyanide), which transmits all but blue; and the third I fill with a purple or puce (preferably aniline puce dye), which transmits all but yellow, or I may fill the three slides with such other liquids as shall be found to possess these properties.

The first of these colour screens is now hung by loops attached to its upper corners immediately inside the lens of a camera, and a colour-sensitive gela-

time dry plate is exposed behind it, giving as a result a picture in which the red solar rays have had no effect at all.

With the second screen a picture is obtained in which no blue rays take effect, and with the third no yellow rays take effect. On developing these images certain striking differences are noticeable between each. From these negatives prints are next taken by contact, on paper coated with bichromatised gelatine, or on glass coated in the same manner (colotype process), and in the former case the image is transferred to the lithographic stone. Each picture is now inked up with rollers and lithographic ink of a transparent and brilliant character, complementary in colour to the colour of the screen under which the negative was exposed. Each colour is next printed in turn on to the same piece of paper, exactly as in chromo-lithography, and the result is that the red ink takes those parts of the picture where nothing showed through the green screen, and no effect was produced on the green plate: the blue ink takes the parts where the orange cut off the light, and the yellow ink those parts obliterated by the purple screen. The resulting point, if the colours of the colour screens and of the inks have been exactly balanced, will be found to portray all the colours of nature, as the secondary and tertiary colours, and the deep tones of the shadows will be correctly given where the pure primary tints overlap. These coloured pictures may also be printed in gelatine tissue, stained to the requisite colours after development, with aniline or other dyes, and the three skins superimposed, for magic lantern slides and the like.

Having now particularly described and ascertained the nature of my said invention and in what manner the same is to be performed, I declare that what I claim is:—The process for obtaining the true reproductions of the colours of nature in a compound photographic print, as hereinbefore described and for the purpose set forth.

[Wherein does this differ from Leon Vidal's method published many years ago?—Ed.]

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AUGUST 8.—Mr. A. Pringle in the chair.

Mr. Dresser showed some lantern slides of instantaneous subjects, including one of a dog climbing a tree. The exposures had been, some of them, as rapid as the two-hundredth part of a second. The detective camera used for the purpose was shown. The high speed was obtained by hooking an additional spiral spring on to the moving part of the shutter.

Mr. F. P. CEMBRANO said that he could corroborate a remark made by Mr. Cowan at a previous meeting with regard to the eikonogen developer, namely, that the solution with sulphite of soda and without carbonate of soda would develop a plate, and that in a reasonable time.

The CHAIRMAN said that in his experience with eikonogen the images came like those of ferrous oxalate, clear and bluish in tone, but with no density.

Mr. S. G. B. WOLLASTON had had the like experience.

Mr. CEMBRANO said that the addition of a small quantity of bromide gave density. He also thought that there was too much soda in the formula supplied with the eikonogen.

Mr. A. COWAN said that he obtained more visible density in the same time of development than with pyro. If the negative was under exposed he had found it to come desperately dense. He thought some plates worked better with a little bromide, and agreed with Mr. Cembrano as to the desirability of using less soda.

Mr. DRESSER referred to the hydroquinone developer, which he considered useless for instantaneous work, but excellent for positives.

Mr. WOLLASTON inquired whether any member could suggest a practical means for varnishing film negatives (those on celluloid) that would not bear the heating required by spirit varnishes.

Mr. W. E. DEBENHAM suggested the use of a varnish recommended by Mr. Ashman, consisting of japaners' gold size diluted to a proper consistency.

Mr. COWAN thought that that varnish should answer well; it did not require heat, was perfectly impervious to water, and could be laid on with a brush. Another plan would be to use a water varnish, flooding the film with it whilst wet.

Mr. F. A. BRIDGE had found gold size diluted with turpentine form a splendid varnish for Eastman films.

Mr. WOLLASTON said that the tendency to curl of celluloid negatives might be overcome by flooding them with glycerine and water.

A question was read:—"What is the best position for an instantaneous shutter in the case of a lens having spherical aberration?"

Mr. DEBENHAM said, a shutter working between the lenses and opening from the centre.

Mr. R. J. EDWARDS endorsed this view.

The next question was:—"In the case of a lens having positive spherical aberration and used with a diaphragmatic shutter, should the focussing be done with full aperture?"

Mr. EDWARDS said that the diaphragmatic should be set halfway.

Mr. DEBENHAM considered that it should be in an intermediate position, but at what particular point would depend upon details not furnished in the question.

Mr. EDWARDS said that he found, and could prove on the blackboard, that with a passing shutter moving at a given rate, and having an opening of the size of the opening of the lens, there was just twice as much movement photographed when the shutter was close to the lens as when it was close to the plate. He illustrated his statement with a drawing.

Mr. DEBENHAM said that with an ideal shutter—one in which the opening and closing was instantaneous, and the time of remaining open only to be calculated—there would be no difference wherever it was placed. With a shutter having the small opening supposed by Mr. Edwards there would be for each part of the plate a longer exposure when used in the lens than when used next the plate; but, on the other hand, in the last case the plate would be exposed in sections, and the whole time of exposure would be much longer than in the other position. The effect of this was to falsify the result, so that a vertical object crossing the field would be represented as slanting instead of perpendicular. He held that the best form of shutter was one in which the time of remaining entirely open was long in proportion to the time of opening and closing, and that the position which allowed the shutter to be smallest, and, consequently, least liable to vibration, was for it to be close to the lens.

LEWES PHOTOGRAPHIC SOCIETY.

AUGUST 6.—The President in the chair.

It was decided that the future meetings of the Society should be held at the George and Dragon Coffee Tavern, High-street, where both ordinary and committee meetings could be held; and a vote of thanks was carried to Mr. J. M. Smith for lending the Glee Room for ordinary meetings, and also to the President for allowing the use of his room for committee meetings.

An excursion was arranged for August 15, the place selected being Barcombe Mills.

Particulars of the excursion to Sheffield Park on August 2 were given by Mr. J. Tunks. Six members attended and thirty-eight plates were exposed.

A discussion then ensued on *Defects in Plates*. Several members called attention to the marks on the edges of plates caused by packing with cardboard inserted between each plate. The excellent way in which Messrs. Thomas & Co. pack their plates was spoken of, and a wish expressed that other makers would follow their example. Other defects commonly found were discussed. A batch of plates by a well-known maker seemed to be very bad, several members bringing plates which had the gelatine film very much stained, one being a bright crimson; and it was proved that these stains were not owing to development but must be in the emulsion.

Several members brought negatives and prints.

The first annual meeting will be held on September 3.

BIRKENHEAD PHOTOGRAPHIC ASSOCIATION.

AUGUST 8.—The President (Mr. Paul Lange) in the chair.

Mrs. Matthew Webb, Miss M. Jackson, and Mr. H. S. Nicklin were elected members of the Association.

Mr. C. B. READER reported upon the excursion to Hawarden on Saturday, July 27. The party numbered about forty (including ladies). Arrangements had been made for wagonettes to meet the party at Chester to drive to Hawarden, where special permission to photograph had been obtained by the Hon. Secretary (Mr. J. L. Mackrell). After tea several groups of the party were taken. The number of exposures for the day were upwards of two hundred. It is intended to present the Right Hon. W. E. Gladstone with an album containing some of the pictures taken on this excursion.

The President had chosen this occasion for his prize medal, the conditions being that each member was limited to six exposures only, and that six results must be produced to be eligible for competition, the principal point in adjudication to be artistic selection of subject.

The PRESIDENT then stated that the Judges (Messrs. T. Comber, J.P., D. Cunningham, Talbot Kelly, and A. Cox) had unanimously awarded the silver medal to Mr. Mackrell, Mr. G. Latimer coming second in order of merit, this being the second consecutive year that Mr. Mackrell had won the medal for the outdoor competitions.

Mr. LATIMER exhibited his half-plate camera with an adapter he had made himself, enabling him to produce from quarter to full-plate direct negatives with the same. In reply to a question, Mr. Latimer stated that he only used a half-plate single lens for all his work. Stopping down, he found that good full-plate negatives could be obtained. He also exhibited several excellent pictures taken with this camera, including full-plate.

Mr. F. N. EATON exhibited several novelties, including camera stand with self-contained head and rigid adjustment for interior work, cutting shapes and table for making lantern masks, also a number of specialities, forwarded for exhibition by Mr. W. Tylar, Birmingham.

Mr. W. Tomkinson exhibited an instantaneous shutter made by Mr. H. S. Nicklin, an amateur of two months' experience, the special feature of the shutter being the great rapidity at which it could be worked.

Mr. J. A. FORREST then spent some little time in giving his ideas of the great advantage that would be obtained by the members, especially beginners in photography, in giving a course of short lectures during the winter months, demonstrated practically, one evening in each week, in the Association Rooms, on such subjects as art, optics, chemistry, &c., the Association being possessed of such excellent workers in all these branches, that there would (in Mr. Forrest's opinion) be no difficulty in arranging the same.

After a little discussion on this point it was resolved to leave it over for further consideration.

The Hon. Secretary distributed several samples of Mr. Oldham's dry powder developer.

The PRESIDENT made an apology for the non-attendance of Mr. W. B. Beaton who had promised to give a demonstration.

Correspondence.

Correspondents should never write on both sides of the paper.

AUGUST MEETING OF THE PHOTOGRAPHIC SOCIETY OF FRANCE.—SOUVENIRS OF DAGUERRE.—A RAPID SHUTTER.—A BANQUET AND SOIRÉE.—THE HOLIDAYS.—AN INSTRUCTIVE PROMENADE THROUGH THE PHOTOGRAPHIC EXHIBITION.—THE INTERNATIONAL PHOTOGRAPHIC CONGRESS: ITS FIRST MEETING AND ITS DOINGS.

The Photographic Society of France held their monthly meeting on Friday evening, the 2nd instant, M. Davanne in the chair. M. Balagny made a donation to the Society of negatives obtained at Bry-sur-Marne. These negatives, as well as the proofs, were examined with great interest, bringing to mind, as they did, the souvenir of Daguerre. One proof attracted particular attention. It represented the interior of a cathedral, and the Secretary gave the following interesting notes on the subject. It appears, said he, that the Village Council were in despair at having such a poor place for worship, and endeavoured in vain to raise a subscription to build a church worthy of the village. Daguerre, who was one of the members of the Council, offered to double the size of the church without the aid of the parishioners. His colleagues thought he had gone mad. On a fixed day they were invited to mass, and were surprised and astonished to find themselves in a church unknown to them. Daguerre had painted a canvas behind the altar representing all the columns and archways of a cathedral, in which the perspective was so artistically given that the illusion was complete. Daguerre had, as promised, doubled the size of the village church. The second view represented the exterior of the church. The third the entrance into Daguerre's residence—all that now remains, the house having been pulled down. The fourth, an artistically-made grotto, supposed to have been built by himself. The fifth, the reproduction of his tomb in the graveyard of the village.

M. Flenry Hermagis, the well-known optician, presented an instantaneous shutter placed in the centre of the lens. This shutter is, as it were, fired off by means of a trigger, and is reputed to be the most rapid in the market. M. le Commandant Joly sent a communication on coloured screens. It was recommended to employ in front of the lens a yellow-tinted glass made by a certain house in Paris, who have succeeded, it appears, in manufacturing a coloured glass of the right tint and quality.

M. Duchesne spoke on hydroquinone, and a discussion turned up on the two denominations, "pyrocatechin" and "brenzcatechin," but there was nothing new to be gleaned.

The President informed the members that 100,000 pigeons would be let loose on Sunday morning at nine o'clock in the Jardin des Tuileries—a good chance, said he, to do rapid work.

The President drew the attention of the members to the fact that the International Photographic Congress would hold their first meeting on Tuesday afternoon next.

The President then spoke of the forthcoming fête in honour of the fiftieth anniversary of the introduction of photography. A banquet and reception to take place on the 19th of August, under the auspices of the Society, the Chambre Syndicale, the Photographic Club of Paris, &c. &c. The price of admission to be thirty francs. This heavy sum will keep it very select, but will prevent many from fraternising and deprive them of the pleasure of joining their colleagues, which is to be regretted.

The President informed the members that the next meeting would be in the month of November.

The members of the "Chambre Syndicale de la Photographie," conducted by their President, M. Vidal, paid a visit to the Exhibition last week. The President pointed out and explained to the members all the different processes. No one could do this better than M. Vidal, he being the reporter of Class XII., and naturally his opinion goes very far on the subject. I will not state his opinion on the French section, but will quote the words of *Le Moniteur de la Photographie* as regards the foreign section. "They, above all, admired the artistic proofs of Messrs. Thomson and Vanderweyde, photographers, of London, as well as the polychromic proofs of Orell Fussli, of Zurich. The fine collection of the Geological Survey of the United States was also very much admired.

This impartial appreciation is the more to be noted as England held back as it were, and few would compete. As to quantity, the British exhibition of photography, as I said before, is not worthy of so great a nation; but as to quality, the exhibits, though few, are gems, and have drawn general admiration, which is in itself a consolation.

The system of going round in parties under the guidance of a competent person ought not only to be recommended but encouraged, as something good must come of such teaching.

"Le Congrès International de Photographie" held their first meeting this afternoon under the presidency of M. Janssen. In opening the Congress the President thanked the foreign members for coming so far to assist at the meetings, and welcomed them heartily. M. Pector, the Secretary, then gave the history of the Congress—how it came to be thought of, its failure at Brussels, and its resurrection in Paris. He stated that 300 members had subscribed towards the expenses. Very few foreign members were present. I observed Messrs. Warnerke, La Manna (from America); Gylidon (Sweden); Petersen (Denmark).

After having read the programme, the work began, not in the order as we find it in the preliminary report, but with the seventh and eighth

questions, the study of which was confided to the third commission—M. Léon Vidal, reporter.

The propositions of the commission were accepted; and voted without great difficulty as regards the seventh question. As to the eighth, many difficulties came in the way. In the first place, the Commission proposed that the prefix "photo" should always represent the action of light, natural or artificial, which was accepted.

That between that word and the affix "graphic" a word should be placed, representing the process employed; for instance, the designation photo-collo-graphic will replace such names as glyptographie, phototypie, autotypie, &c. This also was adopted.

An exception was made in favour of the word photoglyptie. A discussion here began. I expressed the desire, if an exception was admitted in favour of that process, that it should be called Woodburytype, in honour to the inventor. The President said that names of inventors could no longer be tolerated; photography takes no longer the name of Daguerre, &c.

The denomination "*Procédé au charbon*" had the honour of a long and painful discussion, no two being of the same opinion. As a half term, "*procédé au mucilage*" was accepted, although I endeavoured to insist upon its being called photo-collo-graphie *au poidres*; some long names, such as photo-chromatographie and photo-chromographie *à la sanguine*, &c., having been mentioned. M. Warnerke gave his opinion that it would be better to shorten rather than lengthen names; he would propose in that order of ideas to call hyposulphite of soda, hypo. "This shop language cannot be tolerated," said the President. M. Cornu proposed that the bureau should make a kind of photographic grammar as it were: in the first column having all the names known in photography, and in the second column the correction of such names according to the rules as set forward by the Commission.

Thus ended the first meeting. The second meeting is to begin tomorrow at two o'clock, at 76, Rue des Petits, Champs.

PROF. E. STEBBING.

LIMELIGHT MATTERS.

To the Editor.

SIR,—Your paragraphs about Brin's oxygen remind me that I have been anxious to ask those of your readers who are in the habit of using this gas for their lanterns what their opinion and experience is as to its *uniformity* of purity or quality since its introduction into regular use. My own, gradually and reluctantly arrived at, is that a great deal of the gas sent out contains twenty to twenty-five per cent. of nitrogen, and is seriously inferior in illuminating power to that made in the old way from chlorate of potash. Several experienced lanternists whom I have asked are of the same opinion, and I also know that at least two London opticians are seriously intending next season to resume the pumping of chlorate gas, if they can possibly manage it, at the sacrifice of considerable profit.

I would not be misunderstood about this. There is no doubt whatever that the Brin process *can*, and often does, produce practically pure gas. The very first lot I ever used of it was excellent in quality, and struck me as better than usual; but this quality would appear to depend a great deal upon the workmen who carry out the process. It is even possible that the impurity I suspect may not be very visible in ordinary lantern work, though several exhibitors have told me differently. But on several occasions during the past twelve months I have been annoyed by mysterious failures to get "a good light" with my projection microscope. One time the light would be very good, and at another time not, under circumstances which seem to me to point conclusively to the oxygen as in fault. I chiefly use gas from bags, for various reasons; and I have noticed that whereas with chlorate oxygen, and also whenever the light from Brin's is good, the hydrogen tap of the jet may be turned full on, and the oxygen has to be turned a little off to balance it for the best light. Whenever I am disappointed in the light, the oxygen has to be turned full on, and the hydrogen turned considerably off to balance it. I fear this leaves no other conclusion open than that the oxygen is considerably diluted, and my object in mentioning the matter is the hope that doing so may lead to greater care being taken to keep up the quality than seems to me to have been sometimes the case. That the gas is *often* all that it should be I know perfectly well, and we all owe so much to Messrs. Brin for cheapening the cylinder supply that it would be a grievous pity should occasional carelessness cause any permanent want of confidence in it.

Zirconia.—Your old correspondent "Free Lance," some little time ago, mentioned with interest a new preparation of zirconia in discs, in platinum capsules, as supplied by Messrs. Schmidt & Haensch, of Berlin. I am sorry to say that much cannot be expected of them so far as illumination is concerned. They only cost ten shillings each—a moderate enough price—and are very convenient for many purposes. But though the reddish colour of ordinary zirconia has been got rid of,

and the thin disc undoubtedly gives a better light than the end of a plug as tested by me before, I am sorry to have to report that the light is still not more than half that of a good lime under a powerful jet. I am glad of the disc for some things, but as an intense light it is a failure.

Messrs. Newton and I have since tested yet another sample—the fifth which has passed through my hands, of quite independent manufacture—also hailing from Germany. This was in plugs, used on the end, and was very dry and friable in texture, but shrank rapidly at first under the jet, showing that it had not been perfectly dehydrated. I feel sure it was not zirconia alone, for not only was there no reddish tinge to the light, but there was not the extreme non-conduction of heat we had always found in zirconia samples; the incandescence extended very much farther back, and there was no apparent separation of a thin disc. Whatever the mixture may have been, it was a decided improvement, and we were both of opinion that while the light was still very far less than that of a lime tried at the same time, this was the best sample we had ever had. The plug was only about three-eighths of an inch in diameter, and this surface was not enough to develop the power of the jet, and we were of opinion that if the sample had been made into a thin disc of larger diameter (which would, however, require a platinum capsule to keep it from falling into powder), it would have done considerably better. We were about to suggest this to the German manufacturers, when we were told that the whole matter had been transferred to the Brin Company. I hope, therefore, that we may hear of it again from them, and give this hint as to the best form for it, because my experience of zirconia has now been pretty considerable.

LEWIS WAIGHT.

August 10, 1889.

A "ROYAL" PHOTOGRAPHIC SOCIETY.

To the Editor.

SIR,—I beg through the columns of your valuable paper to make a suggestion which to me seems particularly appropriate at the present time. The Photographic Convention of the United Kingdom will shortly meet in London to celebrate the Jubilee of photography. I suggest that the members of the Convention use their influence to obtain the permission of Her Most Gracious Majesty to form a Royal Photographic Society on the same lines as the Royal Microscopical, Astronomical, and other scientific societies. I feel that the claims of photography for the formation of such a society are very great, and that the carrying out of this suggestion would only be productive of good results. Recent advances in our art-science have given an immense impetus to the trade of the country, and further discoveries will no doubt tend to increase this trade.

A further inducement to increased labours in this direction would be added by offering as a reward for advances and discoveries a Fellowship of a Royal Photographic Society. During this the Jubilee year, photographers could do nothing better to show their appreciation of our art than by forming such a society, the many advantages of which it is not necessary for me to mention here. Trusting that this suggestion will meet with the approval of your readers,—I am, yours, &c.,

Moseley, Birmingham.

JOHN HALL EDWARDS, L.R.C.P.

MR. PRINGLE AND STEREOSCOPIC PHOTOGRAPHY.

To the Editor.

SIR,—I am sorry to have to ask to occupy your space once more in this matter, but Mr. Pringle makes some distinct charges against me which, with your permission, I will answer as briefly as possible; I shall then have written the last word I intend to write on the subject.

(1.) Mr. P. says: "I deny having made any such statements, or any statements bearing such construction as Mr. Heywood put upon them; and I challenge Mr. Heywood to produce the passages where he finds the statements he fathers on me." I accept the challenge, and give Mr. P.'s exact words along with my words which Mr. P. repudiates; it is unnecessary that I should do more.

(2.) Mr. P. says: "Further, he attempts to make out a case for the stereoscope as an instrument conducing to artistic effect simply by holding up statements of mine—partly paraphrases of mine—to ridicule." I did nothing of the kind; I never mentioned artistic effect either directly or indirectly. In my letter last week I mentioned that Mr. P. seemed to complain that I had not done so, and he complains again that I "decline the challenge." I dealt with the stereoscope, which the article professed to deal with, and with nothing else. In the remarks I made at the Manchester Photographic Society, which has produced this correspondence, I confined myself to Mr. P.'s article, which I found printed in the most prominent place in the paper. Except from the mention of it in the article, I knew nothing of the controversy that was being carried on between himself, Mr. Chadwick, and "F. M. S.," and I know nothing of it now. I took the article as I found it, headed *Stereoscopic Photography*, and I am not going to be driven from that subject into another, even by the sneers of the writer of the article himself.

In contrast with myself, Mr. P. says, "Mr. Chadwick is well up in the subject" (he does not say which of the two); and I am glad to be able to

agree with him, whichever he may refer to. I will agree with him whenever I can. He also says that "he (Mr. H.) confesses that he knows nothing," again, I think, alluding to the "artistic effect." I was not aware that I made the confession, but if I did I am glad I did. An old Greek philosopher, speaking of another person, said, "He fancies he knows something, although he knows nothing; whereas I, as I do not know anything, so I do not fancy I do. In this trifling particular, then, I appear to be wiser than he because I do not fancy I know what I do not know." Perhaps Socrates' words may fit this case.

Now for the passages I have misquoted. Under my own name I place all the passages in my remarks which either make an assertion or use a quotation.

HEYWOOD.

In the number dated June 13 would be found an article signed "A. P." on the subject of *Stereoscopic Photography*.

Mr. P. began by announcing that he was about to write a strong communication, at least one which should not be charged as being "weak and misleading."

The article professed to be on the stereoscope, but it was almost as much on binocular vision; and Mr. P. seemed to complain that the Almighty had given men two eyes when (as we may presume he argues) one would have done better. "The true effect," he says, "of atmosphere or distance is to be attained not by more or less looking round corners, which almost describes binocular vision, but by—" something else, no matter what.

Instead of a stereoscope for producing the illusion of solidity, let a person look at a photograph or a painting through a pinhole and he will have "quite as much [of solidity] as is good for him."

Mr. Pringle objected that "a short lane of trees is often by a stereoscope made to look miles long (!), and this illusion can be produced at will if the worker has any intent to beguile."

Therefore, argues this guileless writer, the stereoscope ought to be discountenanced and classed among other toys like "Rupert's drops, Pharaoh's serpents, suckers, &c."

A stereoscope "might interest a scientific observer for a few times," and "might astonish a child or a savage for a few times," and so on.

But the climax of absurdity is reached when Mr. P. declares that he has not looked into a stereoscope for many years.

PRINGLE.

Thursday, June 13, 1889.
STEREOSCOPIC PHOTOGRAPHY.

Our "F. M. S." is doubtless quite well able to defend his own position, but the stereoscope is a pet version of the present writer, and we trust the genial writer who alludes to the article of "F. M. S." as "weak and misleading" will not have the opportunity of calling our remarks weak, whatever other epithet he may apply to them.

The true effect of atmosphere or distance is to be attained, not by more or less looking round corners, which almost describes binocular vision, but by gradation of tones and proper massing and contraposition of lights and shadows.

But if any reader desires an illusion of solidity he may get it to a certain extent by looking at any photograph or painting through a small hole, made, for instance, by bending his forefinger into more or less of a circle and looking through the little hole inside the circle. He will then see some solidity, not so much as in a proper stereogram, but quite as much as is good for him.

A short lane of trees is often by a stereoscope made to look miles long, and this illusion can be produced at will if the worker has any intent to beguile.

We have no wish to deery the stereoscope in its own sphere—i.e., as an educational or scientific toy. Rupert's drops, Pharaoh's serpents, suckers, gyroscopes, model engines, tobacco-pipe gas factories, shilling telegraphs, pith mannikins, electric cannons, all have their uses; while the kaleidoscope is an intellectual, instructive, varying, and perhaps artistic source of edification.

When we look by a stereoscope at a stereogram, if the instrument and the "picture" are as they ought to be, we see an appearance of solidity, an effect of distance which might interest a scientific observer for a few times, which might astonish a child or a savage for a few times. The effects of solidity and distance may be—often are—grossly exaggerated, so much the more striking and the more educational the experiment. But beyond an optical experiment or an "illusion of reality," it never goes nor can go.

Stereoscopy is entirely distinct, essentially, from "aerial effect" or "atmosphere." Our impression is that the stereoscope destroys any "atmosphere" there may be in the prints. It is long since we looked through a stereoscope, but our recollection is that even if our prints seen with the unaided eye showed "atmosphere," that "atmosphere" vanished under binocular observation.

Mr. Pringle says he did not make the statements as I use them, so we may take it that at any rate he did not mean them, and there's an end of it as far as I am concerned. As he has bated so much of the length of his fish I do not mind knocking off something from the size of my tiger, and will say that his article is not a libel on the stereoscope, as a libel to be a real libel must be wilful.

And now I hope I may venture to look again through my stereoscope. Into it for the last thirty-five years or so I have never looked without wonder and delight, and so long as I live, and am blessed with binocular vision, I trust this same marvel and this same delight may remain with yours, &c.,

ABEL HEYWOOD, JUN.

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

To the Editor.

SIR,—Allow me to announce that the Opening Meeting will take place on Monday evening next at St. James's Hall, at six o'clock. The proceedings will include the Opening Ceremony and President's Address, Conversation, and a Lantern Exhibition. Members are entitled to one lady's ticket admitting to the opening meeting on application. Excursions have been arranged as follows: Windsor Castle and Town; Richmond and Hampton Court; Kew Gardens and Observatory; Boat Excursion (down river); Greenwich Hospital. Permission has been obtained to photograph at all the above places.

Papers will be read each evening, followed by a lantern entertainment. Tickets of membership and programmes can be had on application at Tree's Office, St. James's Hall, or to, yours, &c., J. J. BRIGNSHAW, 128 Southwark-street, London, S.E., Aug. 15, 1889. Hon. Sec.

Answers to Correspondents.

* * Communications relating to Advertisements and general business affairs must be addressed to "H. GREENWOOD & Co.," 2, York-street, Covent Garden, London, W.C.

All matters for the text portion of this JOURNAL, including queries for "Answers" and "Exchanges," must be addressed to "THE EDITOR," 2, York-street, Covent Garden, London, W.C. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.

J. H. MANN.—Thanks. Will you kindly undertake such an article?

CAUSTIC.—Dishes varnished in the manner described will answer every purpose.

CHAS. STEVENS.—Surely it is a mirage; the effect is so singular that we must devote some time to thinking it over.

WILLESDEN.—See leading article on another page. All the patents have expired, your informant to the contrary.

DUNCAN, Stafford-street, Oban, requests "A. Y. F." to write to him anent *Researches on Light*, if not already suited.

E. Y.—From the appearance of the prints we think they must have been tampered with; but it will be very difficult to prove this.

WILLOTT.—Gelatine dissolved in a minimum of water, with an addition of alcohol, forms a mountant that does not cause much cockling.

M. O'MALLEY.—Probably if the plates are kept for a few weeks they will lose their frilling propensities; in the meantime there is no remedy but alum.

A. PRITCHARD.—Sea water will not answer for washing negatives or prints unless it be distilled. Better make friends of the steward and obtain fresh water.

S. E. A.—The presumption is that there is no gold in the old toning solution, but if there be it may be precipitated by adding a solution of ferrous sulphate.

H. B.—In copying such a painting as you describe you will certainly find it advantageous to employ an orthochromatised plate with a yellow screen, not too deep a tint.

C. W. LEE.—The properties of the material are similar to those of all developing agents. It is one of the naphthalene compounds, but its makers have not published the mode of manufacture.

B. E. J.—If you will send us an example of your failures in making enlargements on bromide paper, we shall be able to judge where the fault lies. From your letter we can form no idea whatever.

W. S.—How can you style yourself an amateur and at the same time ask us if we consider your charges for portraits reasonable? The prices seem fair, that is if the work is equal to that of professionals who charge similar prices.

J. WILSON asks which is the better method of making enlargements for cheap pictures—collodion transfer or bromide paper.—The latter, certainly. Collodion transfers are only made on a limited scale now, bromide paper has superseded them.

LUX.—The precise lateral dimensions of the mirror could easily be ascertained by drawing on a sheet of paper a line representing the length of the negative, and then from a point representing the centre of the lens drawing lines touching the end of the negative line and prolonging them to the place where the mirror is to be situated. We think that a mirror about twenty inches wide would serve every purpose.

OLD SUBSCRIBER.—The white spots seem to us to be air bubbles. To prevent them, raise up the paper from the sensitising bath after it has been on it for half a minute and rub the surface with a tuft of cotton wool, afterwards refloating the paper.

FERO-TYPE asks: "Is there any developer for producing pure blacks and whites, and if sensitising solutions are ever used for producing sharpness in ferrotype portraits?"—We are totally unable to understand what is meant by either of these queries.

OUTDOOR.—If you use the vehicle exclusively for business purposes it will be exempt from duty, and you will not require a license; but if you employ it for pleasure, even if only occasionally, then the case is different, and the "trap" becomes liable to duty.

B. J. COX.—The article being patented, you will not be able to construct it for your own use without permission of the holder of the patent. The mere fact of your making the apparatus yourself does not absolve you from legal proceedings for infringing the patent, as you appear to imagine.

NIMROD.—It is quite impossible to indicate the quantity of magnesium that will be required for your group. A suitable means of using it would be to form the magnesium into a taper of five or six strands, and burn as many inches of it as may have been determined by a previous trial.

S. B. J. says: "I remember a few years ago a clearing solution under the title of the 'J. C.' clearing solution was introduced, which at the time was said to be very good; can you give me the formula?"—The "J. C." clearing solution is simply alum, two ounces; citric acid, one ounce; water, ten ounces.

G. G. PERRY.—The best plan will be to copy the faded print, getting the best possible negative from it; then retouch the negative. Or an enlargement may be made, and that worked up in monochrome and afterwards copied to the size required. This, on the whole, will be the better method of procedure if many copies are required and price is not an object.

FELIX asks if ordinary gas pipe—"compo pipe"—will do for the worm of a still he is making for the purpose of distilling water for photographic uses.—What is known as compo pipe is not good, and should be avoided. Fine piping will answer. It may be obtained at the wholesale gas fittings warehouses. It is somewhat more expensive than the commoner article.

A. GOULD.—Eighteen feet is too short for a studio, to work comfortably in. With such a length only lenses of the shortest possible focus could be used in taking full-length figures. As there is said to be plenty of space, the building had better not be less than twenty-five feet long. A few feet more would be a convenience in taking groups. The other proportions are very good, except, perhaps, that the roof might be made a foot or so higher.

RECEIVED.—Wilfrid L. Spence, William H. Rau, C. Alfieri, and others. In our next.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—The usual Thursday evening meeting of the above Association will not be held on the 22nd instant, next week being Convention week.

PHOTOGRAPHIC CLUB.—In order that the members of this Club may have an opportunity of attending the Photographic Convention at St. James's Hall, the usual meeting at the Club will not be held on August 21, 1889. Saturday outing at Broxbourne.

IMPORTANT TO PHOTOGRAPH ENLARGERS.—At the Portsmouth County Court, before his Honour Judge Leonard, the Eastman Dry Plate and Film Company, Limited, were sued by a Portsmouth firm of photographers, Messrs. Symonds & Co., High-street—a firm in a large way of business—for 10*l.* damages. Mr. Browne, who trades in the name of the firm, alleged that four negatives which he handed to Mr. Bellsmith, the defendant Company's traveller, to enlarge were meant to be conveyed by that gentleman to London. Instead, however, the traveller consigned them to the post, with the result that they were broken. He valued the negatives at least at 25*l.*, as he had received orders for that amount already from the sitters. One, he said, in answer to Mr. M. Hyde, his solicitor, was the portrait of a middle-aged lady, and he added, amidst laughter, middle-aged ladies valued their negatives more as time proceeded. Cross-examined by Mr. Hume-Williams, barrister, who was for defendant, he said they were not photographs of celebrities, but of people in a first-rate position. Sometimes they had duplicates of negatives, but they had none of these. The negatives were packed in a cardboard box, which was in turn enclosed in a wooden box. Mr. Williams, for the defence, contended that the traveller merely posted the negatives to oblige plaintiff, as when he called they were ready for the post. He posted them exactly as he received them, and when received at London they were not in a wooden box. If judgment were given for the plaintiff, it would be useless for them to attempt carrying on business under the circumstances. Mr. Bellsmith swore that the negatives were not enclosed in a wooden box, but admitted that when he posted them he thought them safe. His Honour gave judgment for plaintiff for 3*l.*

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1529. VOL. XXXVI.—AUGUST 23, 1889.

WARM TONES IN DEVELOPED PRINTS.

At a recent meeting of the Photographic Society of Great Britain, Mr. Warnerke spoke of a method of securing warm tones similar to those produced upon "Alpha" paper with the ordinary gelatino-bromide papers of commerce. The plan consists in developing in the ordinary manner, and after chlorising—or converting into chloride of silver—the image so obtained, redeveloping with a feeble developer, such as is usually employed for such tones.

Between six and seven years ago we made a large number of experiments with this identical method, being led thereto by an article by Mr. H. Y. E. Cotesworth on *Pleasing Tones with Gelatine Transparencies*, under date February 23, 1883. The details of the method described in that article as applied to transparencies were as follows:—A comparatively slow and clean emulsion was prepared in the first place, and an image produced by any suitable developer. After thorough washing, the plate was treated with, preferably, a solution of chloride of copper until thoroughly "bleached," after which it was again well washed. Then, after a more or less prolonged exposure to the light, according to the warmth of colour desired, the image was again reduced by means of a weak developer of citrate and oxalate of iron combined, as then used for chloride plates.

Practically, this is precisely the process sketched out by Mr. Warnerke, only that his is intended for use with paper, and not glass. In place of the ferrous citro-oxalate developer of six years ago, too, Mr. Warnerke substitutes a very weak solution of ferrous oxalate or of hydroquinone, both well restrained, as is now commonly understood, otherwise there is no perceptible difference.

Though the difference between the application to paper and to glass respectively does not apparently present any theoretical variation in principle, yet in practice there is a very wide divergence in the results obtained, or, at least, in the ease with which the desired warm tones are secured. This arises from the nature of the two classes of image, and is easily explained by a brief reference to the *rationale* of this mode of development.

All who have practised with chloride or Alpha papers in conjunction with any of the weak developers intended to give warm tones, will have noticed that in its early stages the image is invariably of a strongly marked red or pink tint, but that in proportion to the time the developer is applied, so does the colour gradually change to black. It is necessary, therefore, to so prolong the exposure of the plate that the developer shall act quickly through a sufficient depth of the film to give the necessary vigour without running out the black tone.

It is well known that the film of sensitive material upon

paper or opal glass must be, in order to give the best results, very much thinner than is the case with negatives, or even transparencies. In these latter cases, a certain thickness of layer is absolutely necessary to give strength of image, while a positive on an opaque basis requires but the faintest deposit to give the necessary depth without heaviness.

It is clearly to be seen, then, that a developed positive image on paper is in the best of conditions to secure the desired result. A sufficiently long exposure being given to produce the red tone, the action of the developer is complete, that is to say, has penetrated the whole, or nearly the whole, thickness of the sensitive layer before it has time to produce the black colour. But in the case of a transparency, with its much thicker layer of material, no matter how long the exposure may have been, the penetration of the developer into the film, in order to give the required extra depth, is so slow, comparatively, that the silver first reduced at the surface passes into the black stage before the process is complete; and though the underlayers, if they are laid bare, which is not difficult, will be found to possess the red tint, the *tout ensemble*, as viewed by transmitted light, is a tone approaching in all probability closer to black than to red.

With collodion images the difficulty in getting the warm tones in transparencies is much less owing to the greater rapidity of the action of the developer as compared with gelatine; indeed, with collodion it is possible in this manner to produce almost any warmth of tone that can be desired or imagined.

Since Mr. Warnerke's reference to the process, we have repeated our trials with bromide paper, as well as with a suitably prepared bromide emulsion on opal; and with both ferrous oxalate and hydroquinone, properly diluted, have gained first-rate results, capable of being toned with gold as readily as an ordinary albumen print.

Chloride of copper—made by mixing solutions of sulphate of copper and common salt—is perhaps the most convenient bleaching solution, but we have succeeded equally well with bichromate of potash to which a few drops of hydrochloric acid have been added.

ECONOMY IN THE PRINTING ROOM.

GENERAL RESIDUES AND SAVINGS.

"I HAVE only received a few shillings from the refiners for a parcel of paper cuttings weighing many pounds, please advise what steps to take," is a sample of a kind of letter received in scores, and our articles on economy would be incomplete if we did not refer to this phase of the subject, though it has

repeatedly been treated in "Answers to Correspondents." As a preliminary, we would say that if our readers would bear one fact in mind, it would be the explanation to this and other apparently anomalous results: The refiners who undertake this class of work—the extraction of the precious metals from photographers' waste—charge not upon the weight of the metal extracted for their clients, but upon the weight of the material it is extracted from. No prominence has hitherto been given to this important factor in residue collecting, but, as may easily be seen, it governs the whole question when small percentages are under consideration. It has long been known that gold exists in large quantities in the semi-rock formations in this country, but the same reason that has prevented the extraction of gold from this source operates in the printing room. In the cuttings from finished prints there is, in the aggregate, a considerable amount of silver and gold; but it is rarely present in quantity enough to render its extraction worth while. We may give it as the experience of many in a fairly large way of business, that finished print clippings are best used to light the furnace with. There are dissentients to this opinion, but it fairly represents the average. Of course, when all silvered paper, waste prints, unwashed and untuned, &c., are reduced at one time, the aggregate will represent a good round sum; it will generally be found, however, that if all the cuttings of finished prints were kept out the total amount to receive from the refiner would be no less, and often more.

It will be observed we are taking for granted, all through this series of articles, that the residues are not reduced at home, and this simply because not many photographers possess either the convenience or the skill desirable in undertaking chemical operations of this kind. Where these conditions do exist, the extraction of silver from the various sources named is an interesting operation. In some hands it is profitable also; but when against the refiner's charge, which will not average above five per cent. on well-collected residues, there is set the cost of fuel, crucibles, fluxes, loss of time, wear and tear, and occasional loss through accident, economy will often be found to lie on the side of employing a refiner.

When we speak of five per cent. as an average cost on well-collected residues, we do not refer to cases where all the dust and rubbish of the room is swept into the collecting vats, and where any kind of paper is allowed to find its way into the receptacle for silver paper. We knew, for example, of a case where all the wrappings of the gelatine plates were, for the sake of "tidiness," all thrown into the box set apart for collecting silver paper, and where, likewise, all filter papers, from whatever source, were deposited.

What is desirable is that every bit of silvered albumenised paper, every filter paper used for filtering silver and gold solutions, and all waste prints unwashed, should be saved and kept apart. We have seen walls scraped periodically near which paper had been sensitised in quantity; we have seen floors occasionally planed in similar circumstances; and quite recently we had submitted to us a piece of wood from a bench top that had supported the floating bath for some years. The wood felt almost like lead, it was so saturated with silver, and the actual sum obtained for its owner, who had the curiosity to have it separately assayed, was at the rate of close upon five shillings per foot, superficial! It was worth while taking any bench top pieces to obtain such a result as this, though, again, it would, of course, be foolish to do so unless there were very strong presumptive evidence of the presence of a considerable amount of metal.

With our observations in view concerning the refiner's charge being based upon the weight of material received by him, and not upon the silver obtained, our often tendered advice to burn clippings and waste before sending to the refiner's will be seen to be founded upon a very solid basis of fact. It will lessen the charge to a most considerable extent. But not only here will economy step in, for railway carriage charges will be reduced when the photographer lives away from the large centres, and has to send his residues by rail. Here let us interpolate a little advice: If there is the slightest reason to anticipate that the value of the parcel sent is over ten pounds, it must be decreased and paid for, as unless this is done the provisions of the "Carriers Act" will come into force; whether justified by law or not, the companies will decline to pay anything at all if a lost parcel be over ten pounds.

We will not here discuss the legal point, we simply advise the best plan to pursue. We were recently told by the representative of one of the largest refiners in the country that a bag of silver paper was missing, and upon inquiry was found to have been invoiced as an empty. At the *dépôt* it was assumed that the contents were waste paper, and they were emptied amongst a heap of refuse and lost! To narrate this is sufficient warning "what not to do." We have now finished treating the question of residues, and will in our next article look upon the subject of economy from an entirely different standpoint.

THE Photographic Convention for 1890 is fixed to be held in Chester, as a locality near to and easy of access by Liverpool and Birkenhead photographers, and as an admirable centre for attractive excursions.

IN his admirable historical *resumé*, given in course of his presidential address at the opening meeting of the Convention on Monday evening, Mr. Pringle has—of course quite unintentionally—omitted giving due credit to one by whom the preparation of gelatine emulsion was so far improved as, in a practical manufacturing sense, to have been in a sense revolutionised. Mr. Charles Bennett was most unmistakably the first to publish a method by which the extreme sensitiveness now characteristic of the gelatine plate was obtained, but his method necessitated a "cooking" of the emulsion which spread over several days. This, it can readily be seen, interposed a serious difficulty in its preparation. But this difficulty was overcome by Mr. W. B. Bolton, who in 1873 proposed a modified method of arriving at a sensitive result in a short period. This he did by subjecting the emulsion to a moderately high temperature for a few hours. This was published in our pages at the time. Its influence was so important on the preparation of highly sensitive emulsion that we think it right that due credit should be given in as public a manner as possible to Mr. Bolton, whose name has in this connexion been omitted from Mr. Pringle's list. Those who wish to have a "full, true, and particular" account of the history and progress of both collodion and gelatine emulsion photography are referred to the leading articles in our ALMANACS for 1879 and 1880.

WE have frequently advocated the more extended employment of photography in cases of litigation; but now we fear in this direction it is falling into ill repute. It appears some of the Courts will not now receive it in evidence of personal identity. In the recent Maybrick case, the Judge refused to receive a photographic portrait as evidence, remarking that as the Divorce Court did not accept photographs, he would not. If photographic portraits are not to be received as a means of identification in the Superior Courts, why should they be accepted in the Criminal Courts? The identity of many criminals is established by means of photographs taken of them while previously in jail. This being the case, it may be asked, Why should photographs be accepted in one case and rejected in another? Possibly retouching, or rather that class of it which destroys all likeness and renders the faces of human beings like those of the wax

figures one sees in hairdressers' shop windows, may have something to do with this.

In the trial above alluded to, much in the medical evidence turned upon the post-mortem appearance of certain portions of the viscera. Had photographs been taken—on orthochromatic plates perhaps—they might have proved of much assistance. The presence, or absence of certain spots or markings would have been beyond doubt. In such cases it is manifest that the negatives must be taken by one who is skilled in this particular class of work, and, furthermore, that they must be absolutely untouched.

PHOTOGRAPHY is employed extensively in illustrating pathological works; but it goes without saying that a few touches of the pencil by one ignorant of the subject might be the means of entirely altering the character of the appearances. In such a case, photography, instead of being an assistance, might become positively misleading.

THE better class of illustrated periodicals are making more and more use of process blocks. Some of these are really very good, and others are just the reverse. When the blocks are made from drawings specially made for the purpose, as a rule the result, if well printed, is excellent; but in many cases where the blocks are made from negatives from nature, they seem to be, more or less, failures. The uniform network, or the dots, give the work too mechanical an appearance; furthermore, more often than not it clogs up in the printing. This is well exemplified in some of the recent issues of the illustrated papers. By the way, we have seen some excellent woodcuts which have been considerably marred by the introduction in the background of a mechanical network similar to that in photo-blocks. It would almost seem that engravers were imitating photo-engraving.

THE Photographic Society of India has announced its intention of holding its third annual exhibition. Particulars of exhibits must be sent to the Executive Committee not later than October 15, but English and European exhibits should be dispatched not later than October 1, those from America being sent a fortnight earlier. All pictures and apparatus must be sent, carriage paid, addressed to the Exhibition Committee, 29, Chowringhee, Calcutta. Medals and certificates of honourable mention are to be awarded, should the judges deem the exhibits of sufficient merit.

In the French Chemical Society's Bulletin, pyrogallol and sulphite solution was recently recommended for a new use—a reagent for detecting copper. M. Aliamet having stated that a saturated solution of sulphite of soda containing a little pyrogallol struck a pink colour with salts of copper. Every photographer is acquainted with the peculiar but evanescent pale rose colour taken by pyro-sulphite solution when mixed with water, and Messrs. A. & P. Buisine have shown that the copper reaction is quite useless—that any salt solution will produce the pink tint; even distilled water is sufficient for the purpose, with the familiar effect we describe above. They explain that the colour is due to the oxidation of the pyrogallol in the sulphite solution, which is always slightly alkaline. What is really remarkable, they say, is that colour should be produced in the presence of sulphurous acid.

THE CONVENTION.

ACCORDING to previous announcement, the Convention held its opening meeting on Monday evening. We noticed, among those present, many members and friends from not only various parts of England, but also from Scotland and Ireland. This is, perhaps, the more remarkable, inasmuch as the general feeling is that the time selected for the meeting this year has not been that which would have best suited the general convenience of the members, many of whom can much better spare a week in June or early July than in August.

There is a fine show of pictures and apparatus of the most improved forms in the hall, of which we shall speak further on.

At half-past seven the Council took their places on the platform, and the meeting was constituted by the retiring President, Mr. J. Traill Taylor, who was in the chair, formally vacating it in favour of the new President, Mr. Andrew Pringle, by whom it was assumed, and who then, after a few preliminary remarks, addressed the meeting as follows:—

I am aware that the President of a learned or artistic body, on an occasion such as this, is usually expected to deliver a weighty address on some subject chosen by himself as being specially within his province or specially congenial to his taste; but in this year, the fiftieth, as I hope to show, of practical photography, the course clearly indicated for me to follow will be to trace before you the history of photography from its birth as a practical science to this, its "jubilee" year. A more momentous story, more gigantic and sudden strides, more at once of patient labour and of brilliant genius, will not be found to mark the history of any science than that of photography. If any science can be compared in these respects with photography it must be that of spectroscopy, and the two have, for evident reasons, gone hand in hand together.

It is difficult to realise here and now that fifty years ago, had the whole world been searched, half a dozen men could not have been brought together able to start or discuss any topic concerning photography, while in this country alone we have now at least ninety societies, numbering many thousands of members, every one more or less conversant with some of the many photographic processes in use in our day. I have been unable to ascertain with anything like exactitude the number of persons now actually engaged in the production of photographs, in the manufacture of photographic materials, in photography as a livelihood, as a recreation, and as an adjunct to other sciences. I can only say that to-day photography supports, amuses, and helps tens of thousands in this country. Let us now look back fifty years.

In 1839 Louis Jacques M. J. M. Daguerre, after many years of labour, partly in collaboration with Joseph Nicéphore Niepce, obtained from the French government a pension for the production of the process we later knew as Daguerreotype. It is said that in January, 1839, Daguerre communicated the details of his process to Arago, a famous scientist of that time, but what we know is that on this very day, the 19th of August, fifty years ago, and probably about this very hour, Daguerre's process was fully divulged to the Académie des Sciences in Paris. But it would ill become me, for the sake of "making a point," to ignore the claims of our own countryman, several of whose processes we are working to this day, while Daguerre's process was never known to most of us, and was long ago relinquished by all of us who ever knew it. On the 25th of January, 1839, the great chemist, Faraday, described to the Royal Institution Fox Talbot's process of photogenic drawing, and on the last day of the same month Talbot himself read a paper on the same subject before the Royal Society, saying that he had produced results practically the same in 1835. Talbot used sodium chloride and silver nitrate on paper, these salts being not unfamiliar to us at the present time. And, farther, when, in 1841, Talbot's claim for patent protection was opposed, it was proved that the Rev. J. B. Reade (the "good old rector," as I have heard him called) had during, if not before, 1839 sensitised his wife's white kid gloves with silver chloride, and, as a result of these experiments, had been led to use galls to render the action more rapid. Talbot's claim in this case was upheld, but in 1843 he made a less successful application for protection, when he claimed the use of sodium hyposulphite as fixing agent; but it was clearly proved that in 1839 Sir John Herschel had shown the use of our familiar "hypo" in photography, having many years previously discovered its solvent action on silver haloids. During 1839, too, Herschel used glass as a support for his sensitive film, though it was not till later that a "vehicle," as we now call it, was used to bear the sensitive salts on the glass. Dr. Pye, in 1839, sensitised paper with sodium phosphate; and, lastly, in this same year Mungo Ponton published in Edinburgh his experiments on the action of potassium chromates on gelatine. Either in 1839 or 1840 *sel d'or*, the hyposulphite of gold and sodium, was used as a toning agent for Daguerreotype plates. Thus we have not only the Daguerre process, but the silver chloride process, a development process, the fixing process, the use of glass, the principle of a vast array of gelatine printing processes, and, perhaps, the foundation of our toning process, all bursting upon the world in one year; and surely I may say that we celebrate with justice the jubilee year of photography.

I must not weary you with details too minute of the course of events following these I have mentioned. I will try merely to point to the most conspicuous landmarks of our history. 1840 saw bromide, and 1841 chloride, added to our silver haloids, the former by Goddard,

the latter by Claudet. Claudet was one of the two photographers then in business in London; Edinburgh had a photographer, Birmingham had one, and in Britain there were only these four.

In 1841 the term "negative," now so well known, was first used by Herschel, and Petzval designed lenses having their visual and actinic foci coincident.

Talbot's calotype process held sway for some years; until 1850 the paper constituting at once "vehicle" and "support" was not even waxed.

We now come to a very important era. In 1849 Le Gray suggested that collodion might furnish an excellent *menstruum* for our silver salts, but the general opinion is that the credit of the collodion process is due to Fred Scott Archer, who certainly used the wet collodion process in 1850, and published his method of using it in 1851. But our friend W. K. Burton has heard the late J. G. Tunny, of Edinburgh—who was a patriarch in photography—say that before Archer's publication Le Gray furnished him—Mr. Tunny—with a practical collodion bath process, and, further, that Le Gray developed with sulphate of iron. For many years wet collodion reigned supreme, and with good reason, for it was a process capable of yielding the very finest results. But the inconveniences attending the use of this process, the vaporous exhalations and the staining propensities of the bath solution, as well as the necessity for cumbersome tents and other paraphernalia, set a cloud of experimentalists to search for some method to obviate these troubles. From Taupenot's process, 1855, to Abney's albumen beer, 1874, much valuable work was done, but in the opinion of most competent judges not one of these processes, not one, indeed, of all the other collodion processes, yielded results equal, on the whole, to the wet collodion process.

The first photographic exhibition was held at the Society of Arts in 1852; the first photographic society was the Photographic Society of London, dating from 1853; the first public photographic periodical was THE BRITISH JOURNAL OF PHOTOGRAPHY, which started as a monthly in 1854.

The next era with which we have to deal was that of collodion emulsion. On September 9, 1864, B. J. Sayce and W. B. Bolton published their unwashed collodion emulsion process; soon after this Sayce seems to have retired from the photographic world, but Bolton has from time to time ever since shone out in some new or improved process. In 1874 he gave us his process for washed collodion emulsion whereby, instead of having to wash each coated plate, we were enabled to wash our emulsion in bulk, and, further, to preserve it in the dry state for a long time.

We have it on record that in 1868 W. H. Harrison made an emulsion with gelatine, silver nitrate, and cadmium bromide and iodide. Mr. W. Jerome Harrison in his admirable *History of Photography*, to which I am indebted for much valuable information, mentions this experiment of W. H. Harrison, and rightly points out that most writers have overlooked this fact of an early attempt at a gelatine emulsion. [Extract from BRITISH JOURNAL was read.] THE BRITISH JOURNAL OF PHOTOGRAPHY, September 8, 1871, contains an article by Dr. Richard L. Maddox, proving for the first time that gelatine emulsion was a fact practicable and accomplished.

A word on Dr. Maddox—my guide, philosopher, and friend. Though for over forty years he has suffered from a distressing malady—always in discomfit, often in agony—these forty years, and more besides, have been wholly devoted to science, and the results of these labours have been ungrudgingly given to the world without thought of gain, and with too scanty recognition.

In 1873 we find Burgess advertising gelatine emulsion, and Kennett obtaining protection for a gelatine emulsion pellicle requiring only to be melted and poured on a plate. Various modifications were introduced during the next four years, but the great event that brought our negative process to the point where it now practically stands took place in 1878. Very many in this audience will remember the surprise created when on March 7, 1878, Charles Bennett showed at the South London Photographic Society negatives on gelatine bromide emulsion produced under conditions that would have been totally inadequate to produce a useful image on any plate previously prepared. Bennett, in a truly magnanimous manner, did not hesitate freely to give his process to the world in THE BRITISH JOURNAL OF PHOTOGRAPHY, March 29; and so fully was his method described, that many present to-night were able almost at first trial to produce results similar to those of the discoverer. Bennett, by prolonged action of moderate heat on the emulsion, altered the molecular state of the silver bromide in such a way that the sensitiveness to light of the silver haloid was vastly increased, and in process of time it was found that a much greater heat applied for a much shorter time to the silver bromide in a less viscous solution of gelatine effected the same desirable change, and in this position our gelatine bromide process

may be said to stand at the present day. Monckhoven, in Belgium, showed that a similar result to that obtained by boiling may be achieved by the use of ammonia, but I may say, speaking for myself, that it seems to me matter for regret that the injurious ammonio-nitrate process was ever made known, for I am convinced that the use of it has done much mischief to commercial gelatine emulsion plate making.

In the details of gelatine emulsion, many improvements have from time to time been suggested. Iodide was added by Abney, chloride was also used, and considerable ingenuity has been shown in contrivances for getting rid of the bye products of the decomposition taking place at emulsification. King used dialysis, Wratten precipitated by alcohol, Plener separated by centrifugal force, and again, speaking for myself, Plener's system elaborated by H. L. Henderson is the one that for certainty, simplicity, and regularity commends itself to me.

Regarding negative processes, it may be said that while processes now obsolete rendered magnificent results (though doubtless the fittest only have survived to attract our admiration), still to-day we get results equally good in all cases, with much more ease and rapidity, and we can now in certain branches achieve results wholly beyond the reach of any process except the gelatine bromide in use to-day.

In printing processes our great want, our great aim, and our great achievement during these fifty years have been in the direction of permanence of result. The albumen paper, in its virtues as in its defects, stands pretty nearly where it stood half a century ago, but we have now several processes of indubitable permanence—the platinotype process, patented by Willis in 1873; the carbon processes, founded on Ponton's discovery of 1839; and the gelatine bromide, and perhaps gelatine chloride processes of later dates.

Paper and other substitutes for glass have always exercised great influence on outdoor photography; from the days of Melhuish's roller slide till the advent of the Eastman-Walker roll holder; from Talbot's calotype to the present day of celluloid films, the matter has been steadily kept in our view. The public mind is now on the alert for a process, said to be achieved, yielding a transparent film capable of being wound on a roller and exposed in a roll holder.

In the province known as photo-mechanical printing we have made enormous strides, but as this subject has never occupied my attention I refrain from discussing a subject of which I am ignorant.

A shortcoming of photography, if possible more serious than want of permanence, has been incorrect translation into monotone of certain colours. Colours found in nature and in painting giving effects of brightness to the eye are rendered by ordinary photography as dark, while certain colours more or less sombre to the eye in nature and used as low tones by painters are represented by ordinary photography as high lights. I have deliberately left orthochromatic, or, as I prefer to call it, colour-correct photography, to the end of my remarks on our technique, because this line of research is at present engaging our chief attention, and because in this direction certainly lies our next great advance.

In 1873 Vogel discovered that certain dyes make photographic plates more relatively sensitive to some of the less refrangible rays of the spectrum. In 1874 Becquerel used chlorophyll, and in 1876 Waterhouse used eosin with collodion plates. 1879 Ives published his system of using chlorophyll obtained from the blue myrtle. On January 8th, 1883, Taillier obtained provisional protection for the use of eosin with gelatine plates, ammonia being used along with the dye. This patent stands at this day, and is worked by an English firm. On December 4th, 1884, Dr. Eder read a most important paper on the subject before the Vienna Academy of Science, and since then he has published several papers, all of the greatest value as contributions to the subject of colour-correct photography. The eyes of photographers in this country were first opened to the advantages of orthochromatic photography by the exhibits at Pall Mall of Dixon and Gray, whose work, however, seems to have been stopped by the Taillier patent I have mentioned. Dr. Mallman in the same year, 1886, gave a valuable paper to the Photographic Society of Great Britain, showing ways of using various dyes so as to produce effects in colour-rendering equal, if not superior, to the results obtainable on commercial plates. The next year saw the entrance of our friend C. H. Pothamley into the arena of orthochromatics, for in that year he read a paper to the Society of Chemical Industry, wherein he described his repetition of Eder's experiments, and his investigation of the group of eosin dyes. Also, he exhibited comparative results which went to prove that the relative sensitiveness conferred by the dyes was even greater than had been supposed. In 1887 Mr. Bothamley first flashed upon our astonished senses at the Glasgow Convention, as all who were present cannot fail to remember. Since

that time he has been the leader of British research into colour-correct photography for general purposes, while Capt. Abney's attention has been turned to the more special line of spectrum photography. I do not hesitate to say that to colour-correct photography we must look for the next important era in photography.

There is a name I have only mentioned casually as yet, but photography must never forget how much it owes to Abney. That scientist does not, I believe, claim to have initiated any absolutely new line of departure, but there is hardly a branch of our science on which he has not left a permanent mark.

Carey Lea's researches have been always valuable. And there is another friend of ours, a particular friend of my own, far distant geographically, but doubtless present in spirit with us now. William K. Burton is young in years—still younger in photography—but he has brought to bear on photography a genius and an energy that have marked his footsteps wherever in our march he has trod.

And close to me is another landmark of photographic progress, not a landmark either, but rather a series of milestones. For a quarter of a century and more Traill Taylor has sat in the Editorial chair, and taken cognisance of every event that has influenced our career; and not a mere idle watcher is Taylor, but an active helper, especially in the branch most congenial to his taste—optics.

I have endeavoured to trace the astounding advances scientific photography has made during these fifty years. Artistic photography hardly permits of similar treatment. But I believe that our art has kept even pace with our science. We see many artistic photographs of bygone years just as we see many unfaded prints, but the average of artistic production has advanced just as the average of technique. Connected with the art education of photographers during these past years must ever be the name of Robinson; by precept and by example he has led us in the right way, even by provoking rivalry and eliciting contradiction he has served us, for his rivals have produced works that, with all their faults, will eventually work for the good of photographic art.

The questions I now venture to ask are searching ones, the answers I shall supply no less momentous if I reply correctly. Might we have advanced more rapidly in science and in art than we have done? I think we might. What have we lacked in past, and what do we require for future advance? *Training.* We require training in science and training in art. Mr. W. E. Debenham has stated, and Mr. C. H. Bothamley has corroborated the statement, and my wish is to emphasise it, that there is in our ranks a sad want, an almost total absence, of scientific methods of research and logical report of our investigations. We are not trained to scientific investigation; we lack the patience to eliminate *singularities* in the causes of our variations in result; we jump at conclusions without safe ground to jump from. Photography is far behind every other science in this respect; papers such as we read and write would never be accepted or attended to by societies cultivating any other science, so far as I know.

So, too, in art, Mr. Robinson has said, Dr. Emerson has shouted, that we want art training; we trust to what we are pleased to call intuition; we despise and shirk study, or, what is far worse, we make no pretence of art, and shoot promiscuously with hand cameras at all and sundry over the face of the whole globe. If photography is to advance we must train ourselves to advance it.

Is there a mind anywhere incapable of finding work or pleasure or help in photography? Is it possible to find a being dead to every branch of our art-science? Surely our resources are wide enough. From the immeasurably great celestial bodies to the infinitesimal microbe everything visible is open to photography. Whatever the eye can see, aided or unaided, photography enables us to depict, and much that the eye cannot see photography will catch. Stars too dim, flight too rapid, wave vibrations too frequent or too far separate for our eyes to appreciate, are all within the recording power of photography. The lightning flash, the quiver of the insect's wing, the cloud-capped mountains, and the bowels of the earth, are all alike amenable to our science. Photography links together the past, the present, and the future; the absent with the present, the dead with the living. Fifty years ago what poor man had a portrait of his wife or children? what mother could look on a picture that reminded her of the features of a son in foreign lands? what lover could carry near his heart *her* portrait? Now, what cottage so lowly as not to have its portrait album, rude though the portraits and rough the album? Art, or, if you prefer it, portraiture, was then for the prince or the plutocrat, it is now for all. This is not a small matter that photography has accomplished, and you and I have helped photography to bring it about.

What science is there that can dispense with photography? Certainly no practical science. The astronomer needs us, the mechanic needs us, the microscopist calls on us, the physiologist

and the pathologist appeal to us for help. The artist has learned many lessons of us, and will learn more. Truly, the influence and the use of photography are universal.

Every one now before me has adopted, or may adopt, some special branch of photography as a profession, as a recreation, or as an aid to some other science. To every one, therefore, I say train yourself to make the best of what you undertake; there is no necessity to undertake too much, but let us have no dabbling nor smattering; make scientific experiments, reason logically from the experiments, and let the world have the benefit. Whatever we may do for photography, photography has done much more for us. There is an old proverb and a homely one, but I commend it to-night to your attention with all the force of which I am capable: *Whatever is worth doing is worth doing well.*

A vote of thanks to the President for his address was proposed by Professor C. H. Bothamley, of the Royal Yorkshire College, Leeds; seconded by Mr. A. Tate, of Belfast.

Thereafter the meeting resolved itself into a *conversazione*, during which there was an organ recital by Mr. James Loaring, L.Mus., F.C.O.

At nine o'clock there was a lantern exhibition on a 25-foot screen. This was conducted by Mr. F. A. Bridge, who, in an admirable manner, gave a running comment on the pictures, which consisted of a selection of views and scenes taken by the members and others during and illustrative of the previous Conventions in Derby, Glasgow, and Birmingham, and the surrounding countries. An agreeable feature connected with this was a running piano accompaniment, introducing airs peculiar to each locality and country, Miss Louisa Pyne presiding at the instrument. The pictures exhibited were by Messrs. R. Keene, A. Pringle, J. W. Ramsden, H. Stevens, J. B. B. Wellington, G. W. Watson & Co., and others.

On Tuesday there was an excursion to Windsor Castle, which, although the weather was far from being what could be desired, was very well attended. This was under the leadership of Mr. F. P. Cembrano.

In the evening the President took the chair, and Mr. J. Traill Taylor read the following paper:—

LENSES FOR HAND OR DETECTIVE CAMERAS.

By J. TRAILL TAYLOR.

A HAND camera implies the extreme of rapidity in its action, as, unlike others, it is held in the hand during exposure instead of being supported on a stand.

To this end the lens must possess certain characteristics—a large angular aperture to ensure luminous intensity, and conjoined therewith a form by which the illumination will, as far as possible, be evenly distributed over the area of the plate. But a large aperture, while securing intensity and consequent rapidity, is unfavourable to other requisites, such as depth of definition, and must therefore be subject to limitation.

The acme of rapidity will be found in a portrait combination, but there are two objections to its employment in outdoor or landscape work. Its components being placed one at each end of a rather long tube, the illumination, great in the centre, necessarily falls off rapidly towards the margin; and when to obviate this defect a stop is inserted, then not only is the special advantage of employing such a lens lost, but a positive evil, a flare spot in the centre of the plates, is also imported, which becomes of an increasingly pronounced nature the more the aperture in the stop is reduced.

Still, this lens is invaluable for operations which are conducted in a weak light, or when the scene or subject is not spread over an extended area, but is confined mainly to the centre of the plate. With a lens of this class the shutter must be driven with great rapidity, for as its angular aperture is, say, $f-4$, its intensity exceeds by four times that of the popular lenses which work at $f-8$, or squaring these apertures, as 16 to 64.

When employed with full aperture, its great light-transmitting power renders the portrait combination invaluable for many purposes. There is one use in particular to which it may be applied when fitted to a hand camera. In many of the narrow and dark courts and alleys of cities such as London, scenes of life, in no place else obtainable, are to be found almost at every door. Here, inversely speaking, the very aristocracy of low life and squalor are to be found rampant. But scenes such as these defy the best efforts of the ordinary detective camera, for, owing to the high walls and the narrowness of the courts, the light which reaches these doorways is too feeble to permit of ordinary instantaneous photography being practised with any measure

of success. Here the portrait lens proves the friend in need; for as I have proved amid the purlieus of Drury Lane, which stand proudly pre-eminent over all the slums of the metropolis, there is no scene which cannot be obtained by its agency, and whereas, on an open landscape scene, only a very limited portion of the field would be sharp, here, owing to the convergence of the subject and the well-known law of conjugate focus, the field on the sensitive surface is flat and the picture sharp up to its very margin.

Before dismissing the subject of the portrait combination as a means of securing snap shots, I would allude to the value of the invention of Piazzi Smyth, the late Astronomer-Royal for Scotland, for flattening the otherwise round field of a portrait lens when working at open aperture. It consists in inserting immediately in front of the sensitive plate a plano-concave lens of suitable curvature and dimensions, its concave surface to the front. Into the optics of its action I need not here enter, beyond saying that it prolongs the convergence of the marginal rays in so much greater ratio than the axial ones as to bring both centre and margin to a focus on the same plane, and thus solves the problem of a flat field with full aperture.

I here submit snap shots taken by a portrait lens to show its inconceivable rapidity when used aright.

The lens which of all others is most employed in detective cameras is that introduced by Professor Steinheil, of Munich, in 1865 or 1866. It is now manufactured by every optician, and is known by a hundred different names, to each of which the prefix "Rapid" is usually attached. Its component lenses are symmetrical, or nearly so, and its images are orthographic or rectilinear, or, in other words, non-distorted. Formed of two kinds of flint glass, instead of the usual flint and crown, it is aplatic, that is, works without a stop with an aperture equalling usually one-eighth of its focus. When a larger aperture than this is employed it is not infrequently termed a Euryscope. Its superiority for landscape or group purposes over the portrait combination consists in its greater covering power with any given aperture.

It is with the smaller lenses of this class that we have mainly to do with hand cameras, and fortunately small ones are amenable to proportionately larger apertures than those of greater dimensions. I possess two paired lenses of this class, which are employed either in a binocular or one or other of my detectives, the apertures of which are $f=5.65$, the focus being 6 inches. The tubes of these particular lenses are unusually short, and hence the illumination is excellent, even at the margins. This leads me to speak of the effect of the length of tube in preventing equality of illumination. The longer the tube the more circumscribed will necessarily be the area of illumination, and rays transmitted obliquely through a tube are much more attenuated than central ones. An axial ray is all right, and it correctly represents the angular aperture of the lens; but in proportion to the obliquity of light from the object so does the intensity diminish, until at length it is cut off and total darkness results. Pictorial effect demands the equalisation of the lighting. This may be effected by the insertion of a stop, not in this case to improve the marginal definition, but to subdue or diminish the lighting in the centre.

But in all cases where a lens is mounted at opposite ends of a tube a sometimes distressing number of reflections are formed. Just take up such a lens and direct it to a gas flame and you will observe at least four images, and, in most cases, a fifth one, between the lens and the eye. Every such image impairs crispness, by which I mean intensity of illumination as against a contrasting blackness. The Americans have coined a name for this, which they call "cutting," whence their term that such and such a lens cuts sharp—by which they mean that it gives sharp definition of a bright something as against something adjoining which is dark. Each and every reproduction of a luminous image between the lens and the focal plane means a lowering of the brightness of the subject all over the plate by the diminution of the darkness of the shadows, and this condition prevails no matter whether the lens is stopped closely down or is worked at full aperture. I am not now referring to a central flare-spot, which is caused by the posterior one of these reflections and which is easily prevented, but to the effect of these reflections over the whole surface.

It is this inevitable effect of having such a combination of lenses in a tube which led experienced opticians to speak of the superior pluck and brilliance of the image obtained by single achromatised lenses, and this leads us to consider the application of single lenses for detective cameras. That such a lens gives brilliance is shown in the foregoing remark. But it gives an equality of illumination surpassing that of all others of the doublet form, unless such doublet be considerably stopped down so as to cause the margin to be impressed by a ray equal to that by which the centre is produced. I am not here taking into consideration the diminution of the light, caused either by its transmission obliquely through a circular hole or of its further at-

tenuation by having, owing to its obliquity, to travel a greater distance than the central rays ere it reaches the margin of a plate, although I quite recognise these as well as the hypothetical loss caused by the oblique incidence upon the lens itself. The single lens, when skilfully constructed, can be made to work with a large aperture—much larger, indeed, than is necessary for many subjects in bright weather.

The one fault possessed by a single lens is that of inequality in its ratio of refraction from centre to margin, producing thus an increasing compression of subject towards the sides of the picture. But in a landscape such distortion is not recognisable. What is all-important in a small photograph, especially one intended for enlarging, is sharpness. There is no negative so distorted but what, in course of reproduction, the distortion may be eliminated. Not so, however, with those in which there is any falling off in definition. This cannot be cured. If the light permit, the distortion of a single lens may be minimised by bringing the stop nearer to the lens. There is no doubt that, as regards defining power and intensity of light, single lenses will answer quite well for hand cameras.

Another class of lens—the simple, non-achromatic lens made of one piece of glass only—is now being resuscitated for detective work. The main difference between an achromatic and non-achromatic lens in photography is this: In the former the visual and chemical foci are brought to a focus on the same plane, whereas with the latter there is usually a distance equalling a thirtieth of the focus between these foci; hence to obtain definition it is necessary, after making the image visually sharp on the ground glass, that the sensitive plate be placed, not on that focal plane, but on one a thirtieth nearer to the lens. By adopting this precaution a very excellent degree of sharpness may be obtained. For cameras in which the focus is fixed, or is effected by measurements and without a ground glass, there seems no reason why simple lenses may not be employed, nay, for that matter they are employed in hand cameras, and that, too, somewhat extensively, as witness the Kodak, Lilliput, and other American cameras, as well as some others in this country. The simple lens can undoubtedly be made to produce extremely sharp work, capable of being several times enlarged without much falling off. Owing to its very simplicity the simple lens possesses excellence *sui generis*; there are the fewest reflections from its surfaces, and it is thin, and therefore little absorbent of light. I have used such lenses a good deal, made by past-masters, such as Joseph Zentmayer, Thomas Ross, J. H. Dallmeyer, Steinheil, and Morrison, some of these constructed for tentative purposes, others commercially. While I do not recommend the employment of simple lenses on theoretical grounds, in practice they may be made to answer quite well. I here submit what may be termed the *reductio ad absurdum* of this class of non-achromatic lens, namely, the two glasses of my *pince-nez* stuck by sealing wax on perforated circles of wood which fit a mount. This objective, when proper allowance is made in the focussing, gives a sharp bright picture, free from distortion and works with a drop shutter.

The President said that a departure had been made from the custom at previous Conventions, and that the paper just read by Mr. Taylor had been printed and was in the hands of those members who applied for them, and this course would be followed with all other papers.*

Mr. Conrad Beck and Mr. T. R. Dallmeyer followed with remarks which we are unable to give this week.

The next paper was—

FALSE RENDERING OF PHOTOGRAPHIC IMAGES BY THE MISAPPLICATION OF LENSES.

By THOS. R. DALLMEYER.

PORTRAIT LENSES.—A good many rules have been laid down in order to obviate the shocking examples one often comes across in portraiture, as well as in "wide-angle" pictures, and I have thought it well to explain the cause of these failures and to endeavour to arrive at a sure means of preventing the bad results thus produced. In portraiture it was advised, many years ago, that in taking a portrait of a given size the focal length of the lens employed should be at least double the largest dimension of the image. This rule was laid down to avoid as far as possible false rendering in perspective.

To start on first principles, take a case of a large head, life size. It is well known to you that in taking such a portrait the camera must

* It had originally been intended by the Council that no publication of any papers should be made until after the close of the Convention, but, on more mature consideration, it was thought well that the press should not be fettered in the slightest degree. Hence our publication of two papers in this number.—Ed.

be wheeled out to double its equivalent focal length and the subject placed at the same distance on the other side of the optical centre of the lens. This particular distance, viz., double the focal length of the lens, holds a very important position in its relation to the law of conjugate foci, in that any other point nearer than this will produce an enlarged image upon the screen, and that any point more distant than this will be represented by a reduction in the size of the object; hence, if the eye of the sitter be focussed for full face, the nose of an ordinary person projecting in front of the eye must necessarily be enlarged, and the ear, further away, must be reduced in scale. By what is called *straining* a lens, these effects of contrast become more and more apparent, and hence it is that although there is a drawback in using long-focus lenses on account of their lack of depth of focus generally, still, the longer the focus of the lens employed, in the given case of portraiture, the better, in that these contrasts are not so marked.

To repeat what is deduced from this generally, it is apparent that the more a lens is strained, i.e., used under conditions farthest away from those for parallel rays, or giving it a temporarily lengthened or forced focus, the more pronounced will be the false rendering. As an example of this, I have in my possession a number of old *carte-de-visite* photographs that were taken when the *carte-de-visite* was originally a rage in this country, and I believe first taken up by the late Mr. T. R. Williams. In these *carte-de-visite* most of the subjects are full-length figures and placed at such a distance from the *carte* lens that there was hardly a perceptible difference between the focus for the subject and the focus for parallel rays. Since that time, I do not say invariably, but in *carte-de-visite* taken with lenses of the same focus, there has been a strong movement towards having much larger heads, accordingly bringing the subject very much nearer to the lens, and when this is the case the palpable difference in the conjugate point for the foreground and the background necessarily gives upon the plate an exaggerated perspective. This is sometimes an artifice of the photographer to flatter, for we have all often seen hardly recognisable portraits of thin-faced subjects that have come out comparatively full-faced, simply due to pushing the short-focus lens close up to the sitter.

It appears, then, that for ordinary portrait work it is best to limit the amount of angle taken in, as far as possible, by employing lenses whose foci are at least twice the length of the image, and also to have the subject at such a distance that there is not a too remarkable difference between the corresponding conjugate points of the fore and backgrounds. While speaking on this head, it follows that, theoretically, an enlargement from a portrait taken under the most favourable circumstances is truer in drawing than a direct large head. This arises from the fact that in making the small portrait, taking it for granted that all the rays are practically parallel, they are received accurately upon one plane.

I do not propose to discuss here the *pros* and *cons* of direct large heads as against enlargements, for there are many other reasons coming in, which, at the expense of theoretical benefit, have proved that a direct large head, when taken under the most favourable circumstances, that is, with a lens of long focus, is undoubtedly much more pleasing than an enlarged small image.

View Lenses.—The whole of false impressions given in views, outside the question of imperfectly corrected lenses, hinges on the point of the amount of angle that is allowable to be included on a given size of plate. I have once before pointed out that, from a scientific point of view, a theoretically perfect instrument would be a pin-hole camera having the section of a mathematical straight line for an aperture. Such an instrument would give any amount of latitude in focus and angle of subject included. At a given distance the image or impression received upon the plate thus obtained must, of necessity, be absolutely correct from the one point of sight, but that it be a true rendering of the subject in the image thus obtained from the ordinary distance of vision does not follow at all. Such an instrument can do what the eye of itself can never do. For example, the whole horizon of 360°, by a very short-focus arrangement, could very nearly be taken in in two views of angles approaching 180° each. To imagine the result is somewhat difficult, but as the eyes cannot take in without movement more than from a quarter to a third of the 180°, the subject thus taken would hardly be recognisable from the ordinary distance of vision.

In this connexion the correct amount of angle to be included is, then, the point to be settled. With regard to views, as well as in portraiture, rules of thumb have been laid down, and the reason for this is only due to the desire to make it impossible for the lens to include angles which the eye of itself cannot possibly take in. I think it may be taken for granted that no picture should include more than an angle of 60°, and it would be safer still to never

employ a lens of shorter focal length than the larger dimension of the plate, or slightly over 50°; but it is very evident that the longer the focal length of the lens compared to the greater dimension of the plate, the more pleasing will the perspective become, provided there is sufficient subject of interest thus included. The ordinary distance of vision is about 15 inches, and at 15 inches I am of opinion that the most pleasing size of picture at this distance would be about 10 by 8 inches, but not exceeding 12 by 10. If, then, it can be decided once and for all what is the extreme amount of angle to be included, and this, or always less, is included, we shall never be pained by seeing pictures that, if they are true in drawing from the point of sight of the lens itself, are nevertheless distinctly untrue from the ordinary distance of vision. Taking numerous cases of the falsely rendered results one sees of architectural subjects and interiors on the one hand, and "wide-angle" landscapes on the other, where the distance is dwarfed and does not hold its true value compared to the foreground, it should be borne in mind that if those views could be comfortably viewed at the distance of the focus of the lens they would be true, but angles of 70° to 100° it is impossible, without movement of the head, to appreciate even at that distance. There are other subjects in connexion with artistic treatment of subjects where the form and construction of the instruments employed necessarily come in. Some are self-evident, such as distortion and imperfection in correction for other than central pencils, which of themselves will necessarily give untrue rendering in the structure of the image. Putting a lens entirely out of focus must necessarily destroy structure, but the introduction of spherical aberration in many instances may still maintain the structure of the image but produce a softer effect. I think that this is the only legitimate form of aberration to soften images, although I maintain, at the same time, that a perfectly well-defined or sharp picture throughout is not of itself at variance with softness due to conditions of atmosphere and lighting, the latter remark being, I think, particularly applicable to studies of landscape without prominent figure.

In subject photography in combination with landscape, the employment of a long-focus lens has an important bearing on the standpoint of some of our leading artists, in that the main object or subject of interest focussed for is better defined than either foreground or background, which are subservient, and lead up to the main feature, this of course being dependent again on the position of the conjugates. To obtain truer values also with the long-focus lens in *landscape work*, the subject chosen for the foreground should be sufficiently distant that the correct amount of definition for this should be consistent with that of the most extreme distance or parallel rays, this being often easily attained with large aperture; but if the limits are wide, can only be arrived at by the use of diaphragms.

Another important feature in the employment of long-focus lenses is that it is always much more easy to attain equality of illumination for the whole of the plate, and in this way allow for every part of the subject to receive its full share of light to the extreme edges of the plate, and thereby allowing true values in light and shade.

I have continually used the word long focus in respect to view lenses, but by long focus I simply wish to be understood to mean long focus in the sense of comparison to the base of the plate that it is worked upon. No matter what the form of lens, on a given plate all lenses of identical focus would give exactly the same rendering of perspective. By the optician, lenses are designated "wide angle," "narrow angle," &c., merely from the fact that according to their name it is possible to use them under circumstances for which they have been particularly designed. Records of buildings and interiors, and wide-angle views, are, of course, interesting in their way as mementoes, and lenses are constructed to enable photographers to obtain results that cannot otherwise be obtained by using lenses for their truest rendering.

In conclusion, I would only impress once more upon you that the so-called wide-angle lens should never be employed to its full extent where it is possible for the subject to be treated by a so-called "narrow-angle" or long-focus lens, or the "wide-angle" lens under such conditions that it *practically* is a narrow-angle one.

On this paper some observations were made by Mr. Conrad Beck, Mr. Taylor, of Leicester, and Mr. Gotz.

The usual lantern exhibition was then given.

WEDNESDAY.

The Annual Business Meeting of the Convention was held at 2 p.m. in the Society of Arts Hall, the President in the chair.

After the preliminary business it was announced that delegates were present from the following Societies:—Oldham, Dundee, Manchester Amateur, Ulster Amateur, Yorkshire College, Lewes, Hud-

derfield, Glasgow Photographic Association, North London, London Photographic Club, Camera Club, and London and Provincial.

The President said the next business was to determine upon a place of meeting for next year.

Mr. J. Traill Taylor, in proposing that Chester be the next place of meeting, spoke of its advantages. The fine rooms of the Natural History Society would, he doubted not, be obtained for the meeting. It would also be a fitting place of outing for the numerous brethren in and around Liverpool, whose co-operation should be sought. This was seconded by Mr. Cembrano, and supported by Messrs. George Mason, Bothamley, Samuels, and others, and was carried unanimously. Resolutions bearing on this were proposed by Mr. Bothamley, seconded by Dr. Fallarton, and adopted.

Messrs. W. Benham and Phipps Lucas were elected auditors.

It having been felt that the time of meeting of the present Convention has been fixed too late, it was suggested that, if possible, it be held next year during the end of June or beginning of July.

In the evening the following papers were read:—*Desensitising and Resensitising Albumenised Paper*, by A. Haddon, M.P.S.L.; and *A Suggestion for a Method of Ascertaining the Comparative Rapidity and Printing Value of Gelatino-Bromide Plates*, by Edward Dunmore.

Mr. E. Muybridge then gave his famous lecture and demonstration on animal locomotion. The hall was crowded and many were unable to obtain seats. Mr. Muybridge's remarks and illustrations were of the highest value, but when the animals were shown on the screen in actual (thaumatropical) motion it "brought down the house." Nothing could be better. We shall take early occasion to give a description of the means and appliances by which these wonderful pictures were obtained.

On Thursday excursions were made up the river to Kew and Hampton Court in steam launches, with papers and lectures in the evening.

The Annual Dinner takes place this (Friday) evening in the Café Royal, Regent-street, at six o'clock. An excursion to Gravesend takes place during the day.

The fine display of apparatus and pictures will be described next week, when we will also publish the remainder of the papers that were read.

ECHOES.

"PROFESSOR" HENRY J. NEWTON has been treating the Society of Amateur Photographers of New York to a lecture on the "*Early Days of Amateur Photography*," in the course of which I find "the steam-engine, the electric telegraph, and photography" classed together as "the three great discoveries of the present century." Shade of Worcester! This will be news to thee! I think it must be nearly two whole centuries since you did your share in "discovering" the application of steam to mechanical purposes, perhaps more.

The lecturer says truly, speaking of the bygone days of thirty odd years ago, "that to be a successful amateur photographer meant something very different from what it does to-day." Quite so, but if modern success depends on making pictures on bought plates, receiving medals that belong really to half a dozen other people, and compiling historical or scientific papers to read before "the society," then I should prefer to cast in my lot with the unsuccessful one of years that are gone, when you had to "know how to make a'most everything connected with the production of a photographic print," and frequently had actually to make it. Those were the days when some real credit was attached to the production of good work.

I do not very much like the methods of producing warm tones in transparencies, given in a letter in the issue of July 19, by Mr. Charles Whiting. In the first place, the tones obtainable by acting directly with a sulphide upon an image composed of any of the silver haloids, is, to my idea at least, most unpleasing even when brown tones are liked, which they are not nowadays. The colours so produced are quite different from those obtained by "toning" a metallic image with the same agent. Then, again, the foxy-brown tone given by ferri-cyanide and uranium is simply hideous for any artistic purpose, unless it be very favourably modified by Mr.

Whiting's addition of gold; but the deposit being opaque, it ceases for all practical purposes to be "a warm tone" when projected on the screen.

"Free Lance" has got on to the "eternal ten per cent. solution" question once more, but I do not think his proposal adds much that is valuable to the solution of the difficulty. Ten per cent. solutions, for developing purposes at least, are almost invariably required for use in small if not minute quantities at a time, not in ounces or half ounces. In following Mr. Haddon's plan, ten minims of the solution would contain one grain of the substance, but by "Free Lance's" plan, only a little over nine-tenths of a grain. The ten per cent. solution system cannot be worked for all purposes with the same solution; for developing purposes, Mr. Haddon's method is, I think, the best; if you want to use your stuff by ounces, then adopt "Free Lance's," or, better still, weigh out an ounce right away.

In a paper on *Photographing Interiors*, "W. R." speaks of the possibility of giving several successive exposures by means of magnesium, and especially of securing views of other rooms through doorways opening out of the principal one. This is done by exposing in the first room—I presume closing the doorways in some manner—and after inserting a smaller stop, flashing off a quantity of magnesium in each of the additional rooms. This sounds very ingenious, but how about cross-lighting and half a dozen other objections? A similar method is adopted for combining with an interior a view of the landscape through the window. I should like to have the "pulling to pieces" of the lighting of one of such pictures. Mention is made of using a small stop to ensure definition in the landscape; but what about the definition obtainable with the smallest stop through ordinary window glass?

I am really glad to see the Editor taking up the question of exposure by rule, with exposure tables, &c., which is a subject I have myself referred to previously. Exposure tables and actinometers I hold to be the most mischievous things ever introduced to the amateur, not because there is any harm in exposing correctly or in knowing the precise value of the light, but because they simply will not perform what the ignorant amateur expects of them, namely, relieve him of all responsibility. In the hands of the inexperienced they do more harm than good by preventing the attempt to gain experience, while the practised hand, who alone knows how to properly apply them, can work better without them, *pace* the instance mentioned in the editorial article.

I have read with great interest Mr. T. N. Armstrong's articles on the *Deterioration of Dry Plates*, because I have myself studied the subject with pretty well the same results, namely, that some plates will keep any reasonable time, while others will not keep at all. Like Mr. Armstrong, I started with the opinion that a properly prepared plate should keep, under proper conditions, practically, for ever; and though I have found that films prepared by first-class makers do break down, and that proportionately to their rapidity, I do not attribute the fact to the *rapidity*, but to a failure to exercise *extra* precautions in the process of manufacture.

That "ammonia" plates should succumb more readily than "boiled" ones, for instance, I can quite conceive, but I do not set it down as a matter of necessity. The use of ammonia places the emulsion in a condition in which it is more prone to rapid decomposition than an ordinary "boiled" one, and in which, moreover, it actually contains more decomposed or, at least, soluble matter. Similarly, a rapid emulsion boiled for a long period, or "cooked" at a high temperature, will differ materially in its condition from one digested for a short period or at a comparatively gentle heat. This altered condition absolutely necessitates more careful and thorough washing to remove the soluble and decomposable matters, but, unfortunately, such emulsions are in the worst state to bear thorough washing, and so come off with only just sufficient to pass muster. Such, at least, is my view, and I still believe that a properly prepared gelatine plate, no matter how rapid, ought to keep indefinitely. I am borne out in this by the fact that I, some months ago, found a packet of plates that must have lain *perdu* for over four years, and which were at the time they came into my possession, perhaps, the most rapid ever made, and would compare with the quickest of the present day. These, on exposure, proved to be absolutely as good as when newly made. A few days ago I exposed half a dozen plates whose packing label bore

date "Feb. 1886," and while of the highest rapidity, the quality was everything to be desired.

I note Mr. Armstrong's remarks on the folly of leaving plates in the slides, and also on the effect of emanations from the lining varnish on the sensitive films. Though injurious action may and very probably is so caused, I do not think matters will be greatly improved by Mr. Armstrong's expedient of lining the slides with sensitised paper and exposing to light. Surely no more dangerous substance could be placed in contact with a film of gelatine, especially when it has to be submitted to the action of an alkaline-reducing agent, than a hygroscopic material rich in silver nitrate. If everything were perfectly dry, matters would be bad enough, but as in ordinary circumstances that is an impossibility, I fear Mr. Armstrong's remedy would be worse than the disease.

In his *Photographic Uses of Uranium*, Mr. Thomas Bedding mentions the addition of uranium salts by Colonel Wortley to collodion emulsion, and goes on to say that the same principle was also utilised in connexion with gelatine. The latter is scarcely accurate except in so far as Colonel Wortley did mention such an application, and actually, I believe, exhibited before one of the societies a bottle said to contain gelatine, silver nitrate, and uranium nitrate, to show the preservative action of the last named. But Colonel Wortley never to this day explained how he got the uranium salt to mix with the gelatine without coagulating it, so the method can scarcely with truth be said to have been "utilised."

Paul remarked to Festus, on a memorable occasion, that much learning had made him mad. I do not mean to say that Professor Pickering is in the same condition, but I felt very like Paul must have done when I read the Professor's description of an "Easy" (sic) "*Method of Determining the Sensitiveness of Photographic Plates.*" To "boil the method down," it consists in making a series of stellar photographs of the region about the pole star, and counting the stars represented in each photograph, those plates containing the greatest number being proportionately the more rapid. Professor Pickering himself speaks of the difficulty in accurately focussing in his *easy* method, but, passing that over, I cannot see what data the photographer, whether ordinary or astronomical, would have to work upon in fixing proportionately the sensitiveness of any two plates. We should have to mark them, like brandy, as so many "stars."

What useful purpose is or ever can be served by such contributions as that of "R. W. H." on *A Day's Outing with the Camera in Kent*? It gives no information that could guide, or is likely to attract, an amateur in search of "fresh fields" to go over the ground. It is not up to ordinary guide-book form, and seems only written with a view of publicly recording the writer's gratitude for a day's drive.

JUNUS.

ROUND THE FLEET WITH AN INSTANTOGRAPH.

ARMED with a light quarter-plate camera, fitted up on the instantograph principle, and favoured with a bright sun and a moderately calm sea, I set forth, on the morning of the 31st ultimo, from Southsea Pier, to view the magnificent fleet of ships of war then anchored in the Solent to await the inspection of the Emperor of Germany and suite previous to their dispersion and departure for the summer manœuvres; and surely never did prouder armada ride on the bosom of the deep! Over one hundred mighty ships of war, whose united armaments were potent to demolish every vessel that floats, or destroy every maritime stronghold on the face of the earth, were drawn up in magnificent array—every ship fully equipped and manned, and ready to do battle to the death with either King or Kaiser.

The vessels—"like leviathans afloat"—lay in three lines, anchored between Ryde on the north shore of the beautiful Isle of Wight, and Gilkicker Point on the mainland of Hampshire: arranged in squadrons comprising vessels of various kinds and dimensions, and including first, second, and third-class ships of war, coast-defence ships, gun vessels, cruisers, and last, but not least, thirty-eight first-class torpedo boats—black, murderous-looking craft, that plough their way through the water as though instinct with life, and aflame with the spirit of destruction. I gazed with admiration and delight at the

marvellous array before me, and Swain's poetic and patriotic lines rose to my mind as I beheld it:—

"The ships, the ships of England! what British heart is cold
To the honour of his native isle, to the deathless deeds of old?"

Once on board my steamer—a tug boat called the *Conqueror*, and hailing from the Thames—I applied myself to the important business of securing a favourable standpoint for myself and camera. Having at length secured a snug corner, with a paddle-box as a point d'appui on my right hand, I fired many noiseless, but not ineffective shots at the grand vessels as they passed in review before me. There were at least a dozen steamboats conveying passengers to view the fleet, plying between Ryde and Portsmouth, for more than a week, at various charges. These completed the tour of the armada in from an hour and a half to two hours, commencing the trip by skirting the line of ships nearest the mainland, and steaming between the second and third lines on their return. This offered the best chance to the photographer, for the sun shone brightly upon the ships in the middle line, including the flagships *Northumberland*, *Anson*, *Hercules*, &c., and those turreted monsters the *Devastation*, *Hero*, *Australia*, and others, lighting up their iron sides, showing all their fighting gear with the greatest distinctness, and causing every gun, spar, and rope to stand out in bold relief against their surroundings.

As a great many of these vessels were of enormous length, and as our steamer generally passed them pretty closely, I used a single wide-angle lens, working at about *f*-12, and a drop shutter with its motion reversed, and accelerated by an indiarubber band. This arrangement I found quite satisfactory, and I lost very few pictures through under exposure, or failure to get the whole of the subject into the picture. It will, of course, be understood that my apparatus was manipulated throughout without a tripod, an adjunct which would have been quite useless on board a vessel literally packed with human beings—indeed, to such an extent were the boats crowded, that no passenger cared to risk the loss of his place by vacating it even for an instant.

The naval inspection, which all the world and his wife came to see, was originally to have taken place on Saturday, the 3rd of the present month, but on account of the unsettled and stormy weather then prevailing it was postponed to the 5th. The Emperor of Germany and his fleet of eleven or twelve ships duly arrived at Spithead on the afternoon of the former day, and were welcomed by a salute from the big guns of the British ships, which made, as a Portsmouth *gamin* described it, "no end of a row and smoke."

The beach at Southsea, on the 3rd, was lined with thousands of spectators, who remained upon it "from morn till dewy eve" in the vain hope that the promised inspection would come off. They strained their eyes with every species of "spy glass" to obtain a glimpse of the Kaiser and his following, but they were, for the time, doomed to disappointment, although their enthusiasm was in nowise damped by the humid and gusty weather. On the following Monday—the day of the inspection—two miles, or thereabouts, of the beach at Southsea literally swarmed with excursionists and others, who were determined this time not to be defrauded of their promised treat. Between four and five o'clock in the afternoon a salvo of artillery was again fired, and the deafening sound made the welkin ring. The sailors, who could now scarcely be distinguished through the smoke, manned the yards of the vessels, the Imperial party proceeded through the fleet and steamed on to Osborne, the crowds sent up cheer upon cheer, and the inspection of 1880 was a thing of the past.

If the fleet formed a glorious and imposing spectacle of which every true Briton has a right to be proud, it was scarcely less interesting to behold the myriads of smaller craft flitting eternally to and fro on the glistening waters of the Solent, or the great troopships, such as the *Tamar* and the *Serapis*, steam along—the last-named conveying the "Faithful Commons" to the rendezvous at Spithead. These, however, on account of the postponement of the ceremony, did not take part in the actual inspection, as they had to return to their parliamentary duties.

I obtained, on both days, some successful shots at various sections of the crowd on the beach, and, altogether, the event and its sur-

roundings will not readily be effaced from my mind, or from the memories of all who took part in it, whether as photographers or mere spectators.

C. R.

COLOURED PHOTOGRAPHS.

V.

MORE than at first may appear possible depends upon our closely following these rules as to the general disposition of the complementary colours. Is only by strict adherence to them that we can count, with any degree of certainty, on securing a general *harmony* in our picture. Thus, should we not do so, and through carelessness or want of knowledge place in juxtaposition colours which are *not* complementary one to the other, it will be found that they mutually destroy the natural and inherent beauty which they severally possess. To realise this more clearly, let us wash in a *blue* in close or immediate proximity to a *purple*, and we will find that they mutually detract from each other's individual value or beauty. The reason for this is not very difficult to discover, the purity of tint in each case being marred by its companion. On close examination it will be found that the yellow rays emitted by the purple will impart a somewhat greenish tint to the blue, while at the same time the orange rays thrown out by the blue endow (anything but advantageously) the purple with a slight russet tinge. In both cases a very serious disadvantage, as the purity and natural beauty of both tints, though perfect in themselves, are marred by being placed in immediate proximity.

This rule holds good, also, in the placing of *neutral tints* in contact or close proximity to full hues or tints. These neutral tints should invariably incline in tone to the complementary of such hues or tints as they may be placed besides; for failing this we are sure to defeat our wishes by losing the harmonious effects without which no picture can be deemed successful. As an example of this, take an *olive* tint when placed in contact with a *yellow*. In order to produce the best and most harmonious effect it should incline rather to *purple* than to *green*, the former being the complementary to yellow.

There are many other points well worth our consideration besides the simple contrast of hue or tint. There is the contrast of *intensity*, the skilful treatment of which will at times secure many valuable effects. This will be easily seen if we place two tints of the same colour, but of widely different degrees of intensity, side by side: the deep tint will appear to deepen still more in tone, while the light tint will seem to become still lighter, this apparent difference in intensity being most observable at the points of absolute contact.

All colours when brought in contact with pure white gain depth, for the very simple and obvious reason that the white assumes the complementary tint of the colour placed near it. On the other hand, with black the effect is the reverse, the colours placed in contact with it appear weaker and less powerful in tone. There is a wide difference, however, in the effects produced by the various hues placed in contact with black or on a black foundation. The intensity of the black is considerably influenced and materially modified by contact with such colours as have a luminous complementary. Thus, when purple comes in juxtaposition with black, the depth and brilliancy of the latter is very considerably discounted, owing to the tinge imparted to it by the yellow rays emitted by the purple. Should either blue or green be the colours coming in contact a similar result will follow, the black losing quality by partaking of a rusty tone, caused by the orange or red rays thrown out respectively by these colours. When black, however, comes in contact with red, yellow, or orange, such is not the case—quite the contrary, it becomes more intense and strikingly effective.

All pure colours will be found to gain brilliancy and beauty by the close proximity to or absolute contact with *grey*, which may be considered as a mixture of black and white.

Supposing that we have mastered the difficulties in the way of securing that harmony resulting from the skilful placing in juxtaposition of such colours as mutually lend a charm to each other, also the harmony resulting from judicious contrast, be it of intensity or otherwise, we must not consider that our task, even in this direction, is at all complete. There still remains what may be termed the harmony of analogy. Now this is obtainable by a combination of the various gradations of any one colour in its own scale, or of the hues and tints in the order in which we may observe them in the solar spectrum.

By the skilful arrangement of analogous tints in their most favourable and harmonious relations (and their variety is almost endless) the most charming and effective results may be secured. There are obstacles, however, in the successful carrying out of this treatment,

which render it more difficult of accomplishment than the other two. The effects in question are not so striking—more delicate and subtle as it were—and so demand a greater amount of sound, artistic feeling and keen appreciation, combined with still more skilful management, to secure those really happy and successful results which should be the alpha and omega of the student's efforts.

The laws which regulate the harmony of colours are *not* the outcome of an over-excited brain, or the result of some extremely sensitive organization, which, being endowed with a keen appreciation of the beautiful, has left these rules behind for the guidance of less gifted followers. On the contrary, this harmony is inherent in Nature, and it is she herself who lays down these laws for the guidance of those who seek to reproduce her.

It will require but a small effort to find ample and pleasing examples of the various kinds of harmony. No one can gaze on Nature and fail to see them at every step. This is true alike if we stroll through the fields and make landscape our study, or in the London streets, where, in the study of portraiture, we observe the endless variety of the human face as we pass along, and are forced to confess it an exhaustless study. What a striking study of the harmony of analogy is to be found in the contemplation of the beautifully blended and delicately graduated colours of the rainbow! If, perchance, this most wonderful study of colour and harmony should not have received due attention from any reader, let me advise that the next opportunity be taken advantage of. I cannot think of any combination so complete and so thoroughly showing the balance as well as the harmonies of the various colours. One of the most beautiful rainbows I ever saw was in Dublin Bay lately—the brilliancy of the colours was more than an artist dare put in a picture.

All the principles to be acquired by such observations of Nature are of the utmost value to the art student, and should never be neglected when opportunity serves, whether his ultimate goal be landscape painting or portraiture. Needless to say, it is of greater value in the former branch, but it will be found of considerable advantage also in the latter, and must of necessity in all cases exalt the artistic feeling of the student.

The instruction to be gained from the careful study of almost any landscape is more than considerable. One sees the blue and atmospheric effects of the extreme distance blending softly and harmoniously with the cool greens and greys of the middle distance, while these in turn melt as it were into the warmer and more positive greens, yellows, and browns of the foreground. If on such a landscape we happen on a *setting sun*, what a change, and how still more beautiful the effect. There is a warm glow imparted to the whole scene, every object seems to be beautified by a golden light and a purple shadow. In such a scene the willing and observant student will find endless varieties of effects. In Nature, harmonies of contrast are not hard to find; they are visible and varying at every step; from the wild moor to the fertile valley everything suggests beauty and harmony. One sees the ever-varying forms of the yellow gorse mingling with the purple heather, the scarlet holly berry with its deep (and complementary) green foliage, and the rose, of whatever hue, and its green leaf in harmonising contrast.

In literature the saying goes that "Truth is stranger than fiction," and I, for one, believe it. So, too, in art, the wildest dreams of an artist (worthy of the name) will never suggest anything apparently so impossible as will equal the incredible freaks of Nature as regards both drawing as well as colouring. For wildness of idea and execution I do not think the late Gustave Doré could be well surpassed. He has left us some of the most extraordinary effects in the way of clouds—studies which appear absurd almost, on account of their seeming extravagance, and which I confess appeared to me *impossible*. Yet, the autumn of the year I *was* so impressed with Doré's works, I saw and studied the most extraordinary forms and combinations of clouds I ever saw in my life. They recalled the studies in question, and, I must say, for *extravagance* left them far behind. For violence of colour, too, I may cite a view I had of the Welsh mountains in the early morning. I never saw such strength of colouring, and if transferred to canvas few would believe it real or as in Nature; yet notwithstanding its strength and assertiveness it was harmonious.

All that I have said may be summed up in almost one word—*study*. Study Nature, for she is the only fountain of real knowledge, and if closely observed will teach all that I have tried to place before you. Such principles as are here laid down are only those dictated by Nature, and without observing which we can never truthfully or successfully reproduce her in a picture. As I before said, these hints mostly refer to landscape, but when carefully considered will be found to possess the utmost value in surmounting the difficulties that from time to time will crop up in the painting and arrangement of draperies, accessories, and the general tone and influence of the background.

Much value and beauty can be given to the complexion by the clever and artistic colouring employed in the background, and much depends upon it in producing not only a pleasing, but a perfect and harmonious picture.

Much of this may appear unnecessary, strictly, while on the topic of "colouring photographs;" also, as colouring is mostly employed for *portraiture* in this line, much will appear superfluous, but in the end it will not be so. The object I have in view is to produce a first-rate work (may I say a work of art?) on a photographic base. This must be reached by easy and patient stages, and I trust will be found worth the trouble. Think what an advantage it will give you in the treatment of a picture to have a thorough knowledge of the art generally to support you! How much more easily and successfully will you gain your effects, and, above all, how much more harmonious and artistic will be your picture when finished! If you have any doubts of the value of all this, let me ask you the question, How often can an ungainly figure be made *presentable*, if not absolutely *graceful*, by the artistic treatment of the surroundings?

Another advantage (and though last not least) that is assured by a thorough knowledge of the principles of colouring is *breadth*. As an example of this I can give an experience I had with an artist, some few years ago now, and which will, I think, prove satisfactory on the point. I had an order for two portraits, to be completed by a certain date, companion pictures of husband and wife. I could not possibly get them done in time myself, so I was obliged to give them to a friend. Now, if ever a man knew thoroughly how to treat a background and make a *picture*, no matter what the size, my friend did. Yet, strange to say, in this case, by some unaccountable accident, he painted the backgrounds differently—so differently, indeed, that the pictures did not seem to have been painted on the same size canvases. In fact, you might measure the pictures, find they were the same size, then retire a little distance, look at them, and not believe they were the same size. One treatment, as it were, dwarfed the canvas, while the other gave the idea of *breadth*. When I drew his attention to it, he altered the defective one and made a most successful pair of portraits. It was a pure oversight that let him make such a mistake. Each was *perfect by itself*, but as a *pair* faulty. So much for *breadth*.

This will show, however, that an artist who thoroughly understands the principles of his art can produce on a certain size canvas an effect that will make it appear double the size, and invest it with general importance. In art let us never be afraid of knowing too much, but rather always try to learn more. I have had a fairly long experience in some branches, yet I am always open to learn, and often find strange experiences which repay me for my watchfulness and disposition to still learn.

REDMOND BARRITT.

CLOUD EFFECTS.

THE subject of clouds in landscape photographs crops up, perhaps, as frequently as any subject connected with the pictorial phase of photography. There are many persons who hold the theory that ultimate perfection in a landscape cannot be obtained unless the clouds are rendered as they existed at the time the landscape was photographed—that is, taken simultaneously with the landscape. There is also an equally strong contingent holding a very different opinion. Of the two, I cannot help thinking that, from a practical point of view, those who entertain the first are not close observers of nature for one thing, and somewhat lack artistic appreciation for another. In nature it seldom happens that the forms of the clouds arrange themselves to the landscape with the *best* pictorial effect. Any one studying the matter will soon perceive this. Divest clouds and landscape of colour, and imagine them in monochrome, as represented by photography, and then decide if the position of the clouds, with respect to the landscape, is exactly, or anything like pictorially, as good as an altered position would make them. Cloud effects have, for many years, been a favourite study of mine, and but very seldom have I seen them fit the landscape, so to say, in the *most* satisfactory manner. We may often see splendid cloud effects to wonder at and admire; that is, however, quite a different thing to pictorially and photographically suiting the landscape over which they float. Generally, splendid displays of cloud-forms are looked at without so much as giving the landscape a thought. If it did come in for a share of observation, the probability is, it would owe great part of its beauty to the effect of the clouds above it, and not from any pictorial value in itself. Now, here comes in the principal difficulty and difference. When we are selecting a view for a photographic picture, we desire that the *view itself*, without the consideration of clouds, should compose artistically, and that the principal points of interest shall be centred in this landscape. To do this, certain conditions

must be complied with; the light must fall at some particular angle at some particular time of day and year; its quality must be good, and the foliage must be still. Suppose we are fortunate in getting all these conditions fairly at the same time, it is a thousand chances to one that the clouds will not be present in the best form, *if at all*; the probability is so remote that it is scarcely worth considering. If clouds *do* happen to be right—they do sometimes—well and good, make the most of the opportunity; but it would be a rather hopeless task and waste of time to wait for such a combination of circumstances, especially when clouds can be afterwards added, selected of the exact form and quality to best suit the view, with very little trouble. The only exception that can be taken to this is in the case of sea views, where the water portion is always suitable on account of its power of reflecting light, and its general similarity of form: it is, in fact, a permanent foreground, always ready when wanted, the only thing being to select the clouds whenever they are sufficiently attractive, and the light falls on the water in the most effective manner.

Perhaps, as examples of clouds and landscapes, we cannot do better than study Constable's pictures; he frequently chose large masses of brightly lighted cumulus clouds, whose rounded forms harmonised and contrasted so well with the foliage of the sylvan scenes he loved to paint. This is a kind of cloud, perhaps, best of any for photographic purposes. The pale white cirrus, or the mackerel sky, so often seen at the season of the year when photographers are chiefly occupied with outdoor work, never make any photographic effect worth looking at: they are, in themselves, deficient in contrast, and only add an appearance of spots or smears to the photographic sky, and one that can be matched without detection by the most elementary dodges: a wisp of cotton wool, or a few dabs of colour on the back of the negative will, nine times out of ten, produce quite as good an effect. There seem to be but two kinds of cloud that are photographically useful, viz., the cumulus and stratus forms combined or separate, and the cumulus by preference. It must be understood that I am writing only of clouds in *connexion* with landscape, and *not* as studies of themselves. The criticism, unfortunately too often well founded, that printed-in clouds—clouds taken at some other time and place to the landscape—are untruthful to nature, *entirely* depends for its value on the selection and the skill shown in printing, and not on the process itself. Of course, if the clouds are lighted from one direction and the landscape another, and the clouds happen to be such that particularly emphasise the direction of the light, it is both inartistic and untruthful, and the critics are right: but, providing they are chosen with proper regard to lighting for one thing, and their height above the horizon for another, the printing also being well done, it would be very captious criticism that would raise any objection. My firm opinion is that the most experienced photographer, or artist, could not, in such case, detect *any* points that would be different from a picture that had both clouds and landscape taken at the same time, and with one exposure. The joining of sky and landscape is frequently managed in such a bungling fashion that the most casual examination proclaims the two exposures. A dark cloud enveloping a light building, or other object, that may project above the horizon, is bad enough, but when the clouds are so deeply printed as to be much darker than the middle tones of the landscape, the whole thing becomes absurd. Top-heaviness, is perhaps the most frequent fault in printed-in skies. No definite rule can be laid down as to the depth of printing a cloud negative should have, so much depends on the rest of the picture and effect desired. Dark clouds are generally only suitable for night effects, moonlight scenes, and so forth. Sunset pictures, with *very* dark skies, are untruthfully rendered for the sake of effect, the little splash of light somewhere in the picture being thus wonderfully increased in brilliancy by the gloomy surroundings. Moonlight, alone, will give such great contrasts, for we all know that no matter how dark a cloud appears when the sun is above the horizon, the whole landscape is tolerably well lighted, and in these latitudes for some time after the sun has set. It is only by moonlight that these great contrasts exist. Twilight is a weak diffused light with no bright points, whereas moonlight is a weak direct light with bright points, deep shadows, and little connecting half tints. The manner of imitating a moonlight effect is by under exposing a landscape, with the sun obscured by clouds directly in front, or nearly so, and with water to reflect some of the light, by preference in the foreground or middle-distance. By this means we get great contrasts and little detail. A real moonlight would not be recognised as such, unless the source of light was in front. It is seldom advisable to show either the real sun or moon in the picture, not on account of blurring or reflection, but simply because of the small size these objects are rendered, conveying an impression contrary to accepted ideas. To give

a popular idea of sun or moon, they must be represented many times larger than they would correctly be: painters frequently represent them twenty or thirty times their proper diameter, or even more, yet the effect is neither incongruous or apparently wrong, it only shows how false impressions can be, by habit, preferred to correct ones. A sun represented a sixteenth of an inch in size on a 15×12 landscape would look an insignificant dot, and by the majority of people be considered absurdly small, yet it would be fully as large as a correct representation of the sun ought to be. Distant objects that *we know* are large, invariably give a wrong impression as to size if correctly represented; it is so difficult in such cases to dissociate the real and ideal. We have, in fact, been educated to a certain way of thinking, and stick to it. This exaggerated method of estimation applies to many things other than painting and photography: the real seldom equals the ideal. Perhaps such expanded ideas are a gain to happiness—who can say? It may be a compensating law of nature to encourage perseverance, that all things we are striving after seem larger and better than they prove to be when the striving ceases and the end is gained. At any rate, the representation of distant objects on too large a scale is a pleasant fiction, and I do not think much advantage would be gained by altering it.

Clouds have been almost exclusively used as adjuncts to landscape pictures. They may, however, be used with advantage as backgrounds for portraits to either half or three-quarter length sizes, with a very pretty effect. Portraits in outdoor costumes are very suitably backed with clouds either for solid or vignettéd prints; the different gradations of a suitable cumulus cloud can be advantageously contrasted with the lights or shadows of the dress or figure, and entirely obviate that inlaid appearance so often seen with perfectly plain backgrounds. A delicate retiring background gives great solidity to the figure, and this is why plain graduated grounds suit almost all subjects. The clouds have the advantage of breaking up the uniform level surface without in any degree interfering with the relief, and the whole picture may be printed light or dark, according to circumstances, without destroying this retiring effect. In a well-known picture by Sir Joshua Reynolds, clouds form the only background, and have been utilised by many figure painters to give the effect of distance. The use of clouds in this manner suggests a landscape, although none be present. One precaution must always be taken—never to print the clouds too dark at the upper part, or the whole effect is vitiated. Nothing looks worse than to see a picture overwhelmed with dark clouds, like smoke from a chimney on fire, for no matter how beautiful clouds may be in themselves, they must always, to be pleasing, be subservient to the landscape or figure with which they are associated, and had much better be printed too light than too dark.

If prints are to be mounted it is surprising how slight a tint in the sky will show distinctly. Mounting shows up detail in every part of the photograph that, maybe, is hidden and lost in the unmounted picture. Rather darker printing for pictures intended to be kept unmounted is the general rule, as by this means they look somewhat richer and brighter. It may be borne in mind that a very small portion of suitable cloud in the right place will be one of the most important points in the whole picture. In adjusting clouds to the landscape quantity is nothing in importance compared with suitability—a merely plain tint is infinitely to be preferred to the most beautiful clouds if they are out of keeping with the subject. In printing no sharp-edged mask should be used; a folded cloth laid over the negative and print is all that is necessary, so that the sky and land may be *very gradually* vignettéd into each other. The little time clouds require, or ought to require, to be in printing compared with the landscape will not injure any of the darker parts, even if they encroach on them; it is only when white or very light objects extend above the horizon that any special masking is required, and this may be met with a bit of paper folded to the shape of the object and laid outside the negative in addition to the cloth. Like most other things, correct judgment must be exercised, which, combined with a little practice, renders the work of printing-in clouds quite easy, and the results undistinguishable from pictures where the land and sky have been taken by one and the same exposure. The principal indication of such double printing will be that the clouds are more suitable to the picture than they probably would have been in reality.

EDWARD DUNMORE.

THE SHARPNESS OF PHOTOGRAPHIC PORTRAITS AND ITS INFLUENCE UPON THE ARTISTIC EFFECT.

"A QUIET illumination, energetic technical execution, handsome results?" Much is said about the distribution of sharpness, but it is very seldom that mention is made of the influence of the same upon

the artistic effect. To comprehend correctly this very sore point in photography, let us look on a large head about half life-size or more. Here it is extremely difficult, no matter how carefully we draw the focus, to obtain the artistic rest, it being in the nature of a double objective, that the sharpness extends too much upon a certain surface but not upon the body.

If we look, for instance, at the head of an old man whose hair and beard are mixed with grey, the retoucher will surely almost despair in trying to sharpen hair and beard, because, by the incapacity of the objective, a considerable part is of an entirely inextricable representation, which may even be increased to an enormous extent by the incorrect treatment of the illumination. In smaller portraits we do not observe this so much, and it can be corrected with less trouble by retouching, but the only resource, to evade it on large heads, is by taking a smaller negative and then enlarging it; or, according to Fritz Muller (who was the first to draw attention to it), the front lens of a five-inch portrait objective is reversed, admitting hereby a much longer focus than there is no necessity to come so near the subject to be photographed to obtain the desired size, and thus distortion is avoided. On the other hand, depth of illumination is gained, which by a very uniform sharpness characterised by a delicate gradation, impresses the portrait with the stamp of artistic softness, esteemed so highly in the drawings of the best French artists. If the illumination is correct by application of such a lens, that is to say, that besides the face particularly, the hair will appear naturally, neither black without detail, nor with white spots, such portraits will be unparalleled in their way and require very little retouching, and here alone is proven the superiority of the high combination lens. Because the less retouching is required the better the likeness will be, just as a drawing will be of a higher value by having the least number of lines applied in its production. The single lens, of course, possesses less strength of light than the double objective, but this is, nowadays, sufficiently balanced by our present very sensitive dry plates. But, besides this, the rays of light have to pass only one lens, whereby the light interrupted by the second lens of the double objective is regained, and this is quite a considerable amount.

The illumination has also a controlling influence upon the sharpness, as, for instance, a head (at least on a small scale on account of the objective), and may be so reproduced by illumination, that every single hair, and all other outlines are sharply visible, but a soft illumination will always appear more natural; yet by *correct application*, it can even be considered as the means to idealise, which is never *prejudicial to the likeness*, and thus it has the peculiarity to reproduce softness with definition, and any wrinkled faces with fine gradation. This peculiarity could be ascribed to an effect similar to aerial perspective, the latter having such an evident similarity with it, and the beauty of both being due to very delicate aerial reflections, which we should also try to obtain in every background, and which are produced by placing the background always vertically, at least one to two metres distance, to obtain less sharpness (but still well defined) than in the foreground—"the arrangement"—and finally by bringing the illumination in harmony with the foreground. Those who understand it give to the foreground a distinctly expressed sharpness, and subordinate the middle ground and still more the background accordingly, by a gradual building up of the arrangement, and will impart to their results a fine artistic hue. The sharpness of the background should never be equal to that of the middle ground, and that of the latter should never reach the sharpness of the foreground, as we frequently see; where, for instance, a group is taken with too small an instrument, and where to obtain more sharpness in the lower parts, the ground glass with the upper parts is placed more backward; thus the background will appear sharper above than below. For the same reason the background should always stand vertical to the apparatus, as otherwise the linear proportions, as well as the aerial perspective, will be defective, in consequence of which, the natural as well as the artistic effect will be totally ruined.

BRUNO SAEMANN, *Mullhausen.*

—*Anthony's Photographic Bulletin.*

JACK AND I IN NORWAY.

X.—VADHEIM, NÆRØ FJORD, GUDRANGEN NÆRSDAL, AND STALHEIM.

We got some good pictures of Sande, landscapes full of interest but scarcely so characteristic of the country as many others we had already got. The Sande pictures were more cultivated scenes, lacking the grandeur of the rugged and mountainous parts of the country.

We started for Vadheim—a run of eleven miles—and we just timed ourselves to catch the boat; but it was late, and we had to put in some two hours before it made its appearance. The name of the steamer was *Fram Naes*, a good boat, but awfully crowded, both with cargo and pas-

sengers. There were a lot of Bergen girls on board, with their fancy kerchiefs on their heads, and the everlasting umbrellas in their hands. This article is said to descend from the mother to the daughter as an heirloom, and they were not much to look at either, being as baggy in shape and as nondescript in colour as the veritable Sarah Gamps.

This trip from Vadheim to Gudvangen took us twenty-four hours, and if it were possible to be more amazed by nature's eccentricities than we already had been, it was on this journey, the Naerø Fjord on the way to Gudvangen being without doubt the most impressive series of wonderful effects that even this country can boast. Barren mountains, thousands of feet high, blackening the waters beneath with their reflections, and keeping the light of heaven from descending to their bases; cottages away up two and three thousand feet, looking like toy houses from German toy boxes set down there on the real hills. These shaky-looking things placed in such precarious positions look like a tempting of Providence, for a feeling takes possession of one that a stiff breeze down the gorge would blow the whole farm (for so they name it) to utter destruction, and to try and track the tracing that is pointed out as the road to such a place is almost impossible, the line of it getting quite lost amongst the rocks and boulders that fill the way. The flat parts of the mountain on which such a cottage is fixed look no larger than an ordinary dining-room table. These are the sort of places that they say the children reared in them when out playing are roped to the lintels of the doors to prevent their falling over and being lost for ever. A creepy feeling comes over one when contemplating such places on their fragile footing, buried in shadow, and the reflection comes, "What a poor, miserable, lonely existence! Without companionship, without intercourse." And still they love such homes.

We got a good few pictures on the way, the quay at Underdals being specially successful.

To show how methodically good business-people the Norwegians are, I would cite one case with regard to our telegraphic arrangements. We asked the people at home to telegraph to us at Gudvangen, and it turned out that there was no telegraphic station at the place, but to overcome the difficulty they telegraphed as far as the line would go, and then posted the messages on to Gudvangen, which reached us on our arrival, and without any extra charge.

When we reached the hotel at Gudvangen Jack met two friends with whom he had spent some time at this same place in the previous year. The "Hullo! how do you do?" sounded very much as if they had just been parted for a day or two. They had been fishing but not catching fish, for the weather was far too bright and good. One of these friends was complaining bitterly; he was like the man in Dickens's story who went out to fish for one special perch, but failed to pull him from his watery way. So Jack's friend had been after one fish every day for a week, and had not been able to catch him, although he could see him plainly enough every time he went to try.

The nearness and height of the mountains here quite dwarfed all minor objects, but the air was so clear that very small things could be distinctly photographed at considerable distances.

Next we went through the Nerødal, a mountain pass about seven miles in length. This pass, in its vast and gloomy magnificence, defies description. Rocks huge as houses strewn like pebbles all over the bottom of the gorge, showing the devastating work of many storms, when these rocks had been riven from their holds and tossed about like playthings. The rushing of the river and the perpetual lashing of the falls sounding on the ear like music appropriate to the weird surroundings.

The wealth of subject in this glen, all of a rugged nature, would supply work for the camera for months, and still leave work for months untouched. We could but taste the flavour of it and go on. When we reached the other end of the dal the views were so many and so beautiful that here we halted for an hour or two to bring with us some of the most catching impressions.

Here the way to Stalheim Hotel comes into view, the twining road right in front of us looking almost perpendicular, and zigzagging up hundreds of feet. We had to walk up that wall-like way. After toiling half up the height, we came upon two waterfalls, one on either side the way, with tremendous volumes of water falling from them. We waited on the stolecarré that came trudging up behind with our traps, and made negatives of these, the Stalheim Fall and the Selvé Fall, one of these having a fall of 1000 feet, the other probably 200 feet less. When we reached the top of the road we could see the Stalheim Hotel standing up in the distance on the top of the mountain. We made a picture of it and its surroundings from that spot, after which we found that we were at the end of a "twenty-four band," and had to wait till after dinner to recharge the slide.

This hotel was the most splendidly appointed of any we have yet visited in this country. The dining room was done up with all the latest improvements in furniture, fittings, and appliances, as complete as any dining room in any first-class hotel at home. A verandah was built out from the dining room and covered in with glass, which formed the most charming of coffee and smoke rooms, from which the views all round were magnificent. The drawing and other private rooms on the ground floor were furnished in the most perfect taste, and on the same floor there was a lavatory fitted with all the most improved apparatus. To come upon a house like this on the mountain's top, thousands of feet above the sea level, was rather a surprise.

The girls who waited upon us had each a special duty to perform, and the dinner was served quietly, quickly, and bounteously. We met an American who was taking pictures here with an "Anthony's Detective Camera," and he told us that he had been fairly successful.

The only place we could get convenient for changing our roll was down in the wine cellar amongst hundreds of bottles of wine; they locked us in to perform our magic in the ruby light, feeling sure, I suppose, that we would not make free with the liquor.

Looking down the Naerødal from the front of the hotel was one of the most comprehensive and impressive pictures that could be imagined. Jack took two or three of this view for the special purpose of enlarging on his return, viewing it from a hill about a mile back from the gorge. Mountains from three to five thousand feet high, standing up on either side, forming a shape like a V, with no more room at the bottom than will let the water flow, mountain on mountain standing out clear and defined and stretching away for six or seven miles, with patches of snow and sunshine, and the bald weather streaks on the beaten rock, with here and there a tree, and hundreds of little waterfalls losing themselves in the breeze, whilst along the mountain side comes into view the yellow-marked carriage drive as it twines in and out. This is a rough outline of the subject, and we got good pictures of it.

We took a negative of the waiting-maids serving coffee, but on development we found that they had moved. I was sorry it was a failure.

We started from Stalheim for Vossavangen, and had not proceeded far down hill before we met our lady and gentleman friends of the *Norge* spinning along on their tricycles. They had come from Voss and were bound for Stalheim. They said that they had had a good time, and that in all their journeys only one horse had been frightened by their machines. We stayed for a little at Opheim, next at Venge, then continued our journey, reaching Vossavangen that night, a run of close on forty miles.

We intended to stay at Fleischer's Hotel, but when we reached Voss we found that it had been burned down, and that he was occupying temporary premises in an old schoolhouse that he had transformed into an hotel for the time being.

Mr. Fleischer is known all over the country as a model landlord, and we found, even in this makeshift place, that the visitors' comfort was his first and great consideration. How he managed to stow the customers away was a marvel, and still there was an air of comfort reigning all around. Fancy, in the room where we slept there were eight beds (of course the room was large), and the washing apparatus was arranged on tables down the centre of the room.

A word here about the beds, or the above statement might be misleading. The beds are made very much on the same plan as berths in steamers, only with a headpiece, and standing on four legs, a sort of long box really, into which the mattress and clothes are placed, and you rather lie in it than on it. These bunks are usually made for one person, but in some places I have seen them with a telescopic drawer in front the broad way, which could be pulled to double the width, thus making a bed for two.

The mattress on which you lie is in most cases a very innocent affair. At one of the hotels I stayed (not this one) the mattress seemed so thin that I complained to the landlady about it, when she came, lifted it out of the bed, and threw it over her arm, as easy as if it had been a muffler, when the chaff or whatever stuff was in it dropped down to the ends, leaving the centre quite guiltless of any stuffing whatever. It looked just like a monster purse of the long, old-fashioned kind, with a little money in either end. Away she walked without a word, nor did she look the least surprised, and sent me in another one, which possessed the advantage of really having something in it to lie on; it was well stuffed.

But to come back to Fleischer's house. There was nothing of that kind there; stuffing all round was well attended to. We thought that we would like to give him a picture of the ruins of his late hotel, and went and had a look at it, but it had been so completely burned down there really was nothing left to photograph, not even ruined walls. He is, however, having the new house raised on the spot, which is of more importance to him and visitors.

In a letter I had from him the other day, he said that his new house would be ready by the first of May, and that it would be fitted with eighty beds.

Should you visit Voss, go and see Mr. Fleischer, and you will find in him one of the jolliest of fellows—one who is never better pleased than when putting and keeping his visitors right; and if you wish to know what you should go to see, and how you should go to see it, in this the most lovely of districts, apply to Fleischer; he will show you how to do it, and no man knows better.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AUGUST 15.—Mr. A. HADDON in the chair.

A telegram from Mr. Friese Greene was read, expressing regret at being unable to attend that evening for the purpose of introducing his photographs on opal cards, and postponing the demonstration till that day three weeks.

Mr. W. ENGLAND, on his return from the Paris Exhibition, showed an appliance which he had brought over, called a *porte-rondou*. The object of the contrivance was to enable a lens to be temporarily mounted upon the camera without the necessity for having separate fronts for every flange. To accomplish this object a short tube was used, the inside of which must allow the largest flange to pass it; a second short tube fitted into the first by a bayonet joint, and held firmly in place a disc of ebonite against a shoulder in the outer tube. The disc of ebonite had to be cut so as to allow the back of the lens tube to pass through it, and the flange of the lens being screwed on to its thread until the disc was bit firmly between the flange and mount; the disc was then put into the short tube first mentioned and fixed by means of the bayonet joint.

Mr. A. COWAN said that for cutting circles in ebonite he had found it useful to employ a pair of wing compasses, one point of which had been sharpened; this sharp point in a few revolutions cut completely through the ebonite.

Mr. COWAN then showed some plates developed with eikonogen in comparison with others developed with pyro, bromide, and ammonia, and with pyro and soda. With the latter, and with eikonogen, he considered that for bringing out an under-exposed image there was an advantage over the ammonia and bromide developer of three to one.

A plate was shown having spots of partial opacity all over. It was stated to be the only one out of a dozen packets that had exhibited this peculiarity.

Mr. S. G. B. WOLLASTON thought that the spots were due to imperfections in the glass, and that there were depressions corresponding to a certain amount of alkali left in the glass at those places, which alkali had induced more powerful developing action and caused the spots.

A question was read:—"What is the practical maximum and minimum focus requisite for a half-plate camera?"

Mr. F. A. BRIDGE and Mr. F. P. CEMBRANO said that the range should be from three to sixteen inches.

The CHAIRMAN said that it was desirable that the camera should be long enough to use with one of the lenses of the double combination, and for that purpose eighteen or nineteen inches would not be too long.

Mr. W. E. DEBENHAM agreed with the Chairman as to the length desirable. For general use with an outdoor half-plate camera he preferred a lens of nine inches focus, and to use one of the components of this instrument the camera should be at least as long as the Chairman said, unless, indeed, an adapter was used.

Mr. A. PRINGLE showed a chronograph which he considered peculiarly adapted to photographic work. It was simple, and not expensive, and would time from one-fifth of a second up to ten minutes.

The subject of dust spots appearing on plates which had been carefully dusted before being put in the dark slides was introduced.

Mr. BRIDGE said that these spots frequently arose from the sharp edges of the glass chafing and cutting the wood of the slide.

Mr. WOLLASTON said that he prevented this evil by wedging the plates firmly into place with pieces of a common match.

A question was read:—"What is the best method of mounting prints which are highly glazed so that the gloss may be retained?"

It was suggested that the patent adhesive mounts should be used.

Mr. MACKAY said that it was not necessary to get the patent mounts, as any one could prepare them. Some years since it was endeavoured to obtain a patent for adhesive mounts, but the patent was refused on the ground of triviality.

Indiarubber mountant was suggested, but Mr. BRIDGE said that five times

out of six the prints would soon peel off. A better plan was to use starch paste containing alcohol in large quantity. This was prepared by making the paste very thick to begin with, and adding alcohol while hot. It must also be used hot.

Spirit gum, such as used by actors for fixing moustachios, &c., was mentioned as probably answering to the requirement of the question, and an inquiry was put as to the composition of the mixture, which, however, was not answered by any of the members present.

NORTH MIDDLESEX PHOTOGRAPHIC CLUB.

AUGUST 12.—Mr. Cherry in the chair.

Mr. S. T. Chang was elected a member.

Mr. CHERRY gave a report of the outing to Welwyn, and presented the Club with a portrait of Mr. Valentine Blanchard, executed in oils. He also exhibited some large direct portraits printed in silver.

Mr. Chang exhibited several views of the cycling camp at Godalming, taken with a detective camera and printed on aristotype paper.

At the next meeting of the Club Mr. E. T. Hiscock will demonstrate the platinotype process, printing in sepia also on fabrics. Visitors invited.

BRIGHTON PHOTOGRAPHIC SOCIETY.

AUGUST 13.—The President in the chair.

Mr. Simeon Norman was elected a member, and Messrs. Mitchell, Tate, and Webber were elected to fill vacancies on the Council.

Mr. J. E. MAYALL delivered a lecture entitled *A Spectroscopic Examination of Colour and its Adaptation to Photography*, which was illustrated by diagrams and several specimens coloured by his patent process.

At the conclusion of his address an animated discussion ensued.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

AUGUST 15.—Mr. E. H. JAGUES (Vice-President) in the chair.

The following excursions were announced:—For September 7, to Wren's Nest; for September 21, to Kenilworth.

Mr. Walter Griffiths offered as a prize for the Stratford excursion one of his new lantern-slide cameras. This camera was exhibited and explained by the HON. SECRETARY (Mr. J. H. Pickard), showing how easily and readily lantern slides can be made by reduction with this instrument. There is no focussing required. The negative is placed in the slide at one end, the dry plate at the other end of the camera; it is then taken into the light and exposure given, the ordinary development to follow. The simplicity of the instrument and the slides produced and shown upon the screen were much commented upon.

Mr. J. EDMONDS then read a paper on *Light, Lenses, and Stops* [this will appear subsequently], illustrating the same with the lantern and diagrams, and concluded with showing a number of pictures on the screen, taken under certain conditions bearing upon the subject and remarks *re* lenses, &c.

A discussion followed, which was adjourned to the next meeting owing to the lateness of the hour.

The subject for the next meeting is *Lantern Slide Making*, by Mr. Jagues.

DARLINGTON PHOTOGRAPHIC SOCIETY.

AUGUST 12.—Mr. E. ENSOR presided.

Mr. W. GARRITE BREWIS opened a discussion on *Vignettes and Vignetting*, and illustrated his remarks by several specimens and apparatus used in producing the same.

It was decided to hold an exhibition of "holiday work" at the next meeting, each member to send in two prints.

Samples of Oldham's dry powder developer were distributed amongst the members.

CARDIFF AMATEUR PHOTOGRAPHIC SOCIETY.

AUGUST 15.—Mr. S. W. ALLEN in the chair.

Mr. W. Booth was elected an ordinary member.

The HON. SECRETARY read a mass of correspondence relating to the forthcoming Exhibition, and the promises of support from some of the leading photographers of the day were gratifying to the Council.

The Society having gained some practical and useful knowledge from their first experience last year, will make every effort to give satisfaction both to exhibitors and visitors.

Several practical suggestions by the photographic press are receiving careful attention.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—Monthly technical meeting. Tuesday next, August 27, at eight p.m., at the Gallery, 5A, Pall Mall East.

SAFE TRANSPORTATION OF SULPHURIC ACID.—Herr Bickmann has patented, in Germany, a process for enabling sulphuric acid for manufacturing purposes to be safely transported. He takes advantage of a property of certain salts—of which alkaline sulphates are representatives—by which they give up their water of crystallisation when heated and take it up again when cool; and he does so by mixing the salts in an *anhydrous* condition with a calculated quantity of sulphuric acid. The whole mass becomes granular, or may be formed into cakes; and when heated the whole liquefies and may be used as if it were sulphuric acid, for the presence of bisulphate of soda does no harm.—*Scientific American*.

Correspondence.

Correspondents should never write on both sides of the paper.

POSTAL DAMAGE TO PHOTOGRAPHS.

To the Editor.

SIR,—For many years I have had to transmit through the post numerous articles far more fragile than photographs, and now adopt the plan of attaching a tying-on direction label, with the stamps affixed, to the extreme corner. Her Majesty's servants will then most likely take the package safely in the left hand while aiming their blows at the "Queen's Head" which it is their duty to deface.

If some such plan were adopted in transmitting photographs through the post, viz., the stamps affixed to a loose label, I feel sure there would be less cause for complaint against the postal officials, who can have no malicious intentions in damaging photographs, while it is unreasonable to expect that they can adjust the force of the blow to the nature of either the contents or the covering of the package.—I am, yours, &c.,

Edinburgh, August 16, 1889.

W. II.

NATURALISTIC PHOTOGRAPHY.

To the Editor.

SIR,—In your current issue you reviewed a new edition of one of Mr. H. P. Robinson's works, and quoting his condemnation of the theories advanced in Dr. Emerson's *Naturalistic Photography*, you seem to concur in it. I may, perhaps, misunderstand your critic, but apparently he thinks that the "new heresy" has been stamped out by the prancings of the mighty ones of the old school.

I believe that this is very far from being a true version of the case, for, as a matter of fact, the large majority of press notices have been favourable, and so far as I have been able to discover the opinions of the best artists among amateur photographers, unbiassed by previous utterances, they are for, and not against, the book. However, I am far from wishing to enter into a general discussion of the said work, nor would I willingly endanger the dignities of controversy; but the question of sharp focus seems to me to have been so much misunderstood, or so badly misinterpreted, that the true bearing of it has hardly yet been apprehended, and, with your leave, I will advance a few suggestions on this subject.

Now, the state of the case is this: The scientific basis of the theory no one has yet ventured to assail. It is a verifiable fact that the eye looking at the central point in any scene does not see any detail in the surrounding accessories until it shifts its glance to them. Are we justified in using this scientific fact in making pictures with the camera?

Authority I shall not here discuss at any length, for it would occupy a volume, and is after all not conclusive. The only painters who have used full detail are the Pre-Raphaelites, ancient and modern, and the old Dutch school, and, on the whole, Meissonier and his imitators. Against these set Michael Angelo, Giorgione, Titian, Rubens, Van Dyck, Tintoretto, Velasquez, Reynolds, Gainsborough, Turner, Constable, Crome, Millet, and Corot (to pick a few of the greatest at random). Did these painters slur minor detail because they were unable to render it?—did they not rather render it fully in their earlier periods, and gradually grow looser in their treatment of it when their powers were matured and their knowledge at its height?

Next, what object is there in putting details out of focus? Why not put in a small stop instead of a big one? An artist making a picture is imposing his idea of the scene upon the spectators: he conceives it as a subject; arranges the portions of it so as best to express his meaning; and, in a word, he gives you his version of the incident. Must it not be of great help to him to be able to show you what part of the picture he regards as most important and what other parts are merely accessory? It is true that he can employ lighting and composition to some extent for this purpose, but in photography his control over these is very limited. But by judicious use of focus he can always direct your eye to that subject for the sake of which he took the picture, and not allow your attention to be diverted by the beautiful intricacies of wholly subordinate details. Thus, in a ploughing picture you do not want to see every clod all over the field as sharply rendered as the straining horses or the guiding man, as if the ploughman were set to cultivate a field of lava.

To put the actual subject in focus and let the unimportant details be less sharply focussed thus seems of service when the picture is all that we would choose, but this course is of still greater value when some parts of the picture are such that they would be wholly suppressed or widely altered by a painter. The photographer cannot omit them, but by taking the sharp edge off them he can render them harmless and unobtrusive, and all this, in both cases, not by taking any liberties with nature, but by transferring to paper exactly what the eye sees when it looks at the point at which the artist intended it to look.

Mr. Robinson's contention that photographs should be sharply focussed because rendering of detail is the distinctive quality of photography does not amount to much. I always have thought that the essential advantage of photography was the absolute accuracy with which it rendered the form of everything in front of the camera, and I never heard of any other artist than Mr. Robinson valuing a photograph artistically as such for any but this reason; but this does not prove that it is necessary to give every detail equal sharpness.

That softness of focus "must not be carried to the length of destroying the structure of any object" is a point on which Dr. Emerson has strongly insisted, and in few respects has greater injustice been done to him by his opponents than in their constant disregard of this reservation. As long as structure is not destroyed it is not easy to see how the use of a shallow focus can be abused.

I can only plead my interest in this subject as my excuse for addressing you. If I have not bowed to Mr. Robinson's authority, I am sure he is honest enough to prefer truth to flattery.—I am, yours, &c.,

August 20, 1889.

GRAHAM BALFOUR.

BLACKING THE INTERIOR OF DARK SLIDES.

To the Editor.

SIR,—Mr. T. N. Armstrong has some remarks in your issue of August 9th on the subject of the blacking in dark slides spoiling plates kept in them more than a few hours. This is rather an important subject, and it was years before I found out the cause of sometimes a batch of negatives turning out useless. It was, I now believe, when they had remained in the slides more than an ordinary time. I should be glad to know what one ought to do to a slide that fogs plates. Probably the best course would be to remove the offending substance with sandpaper. Which of the materials in the blacking is it that produces the fog? Why do makers persist in blacking the insides? No light ought to get in, so that no reflection will occur with a properly made slide. Chemical action of the stuff hinges are made of is another source of trouble. American cloth is fatal. One ought to be able to expose a plate without muffling up the camera in the focussing cloth, but I doubt if any apparatus would stand it.—I am, yours, &c.,

F. J. QUICK.

Camera Club, 21, Bedford-street, W.C., August 21.

PORTABLE CAMERAS.

To the Editor.

SIR,—In your issue of the 16th instant is published a specification (No. 11,300) of "an improved portable camera." Part of the description is that of one light-tight box sliding into the other, apparently for focussing purposes and compactness for portability when not in use. I have had a camera on the stocks for about a year with this arrangement, which has been freely described and shown to my photographic and other friends, and also been exhibited at the Photographic Club. It seems to be essentially the same as described in the above-mentioned specification, with the exception that the shutter is behind the lens, and the label disguising the front thereof springs up and forms a sky shade instead of moving to one side, and that the method of setting and releasing the shutter varies.

I have found a finder quite superfluous, and my camera is also arranged for use as an ordinary camera with a focussing screen.—I am, yours, &c.,

HENRY E. DAVIS.

Paulatin Club, 39, Fitzroy-square, W., August 21, 1889.

PACKING DRY PLATES.

To the Editor.

SIR,—In your issue of the 9th instant I notice with pleasure the comments of Messrs. Armstrong and Dunmore on the various methods of packing dry plates. This is a subject, which, in my opinion, stands greatly in need of discussion, as is testified by the all too numerous methods adopted by different manufacturers.

Each of the above-mentioned gentlemen—one directly, the other by inference—condemns the grooved box system, and this quite corresponds with my experience. In fact, owing to this packing, I have been obliged to abandon the use of my sometimes pet plate, the —.

As an amateur, detesting much luggage, I have to carry four or five dozen plates every summer crammed into my portmanteau, which is subject to the usual operations of the baggage smashers, and the consequence was, under favourable circumstances, half a dozen or more plates broken or scratched, owing to pressure on the half-filled cardboard boxes. This sometimes on the return journey! And, besides, one dozen plates in a grooved box occupy the same space as two dozen packed closely. Hence, after some experimenting, I have settled down on a plate packed rationally, and now I never have a loss by breakage while travelling.

If, then, it be conceded that close packing is the correct plan, both for keeping and carrying, it only remains to settle on the best method to adopt. One is the face-to-face arrangement in pairs, either with a paper disc or sheet, or else without any separator at all, between adjacent plates. For my part I don't like this style, as in the dim, religious light used for changing there is occasionally a slight—very slight—difficulty in distinguishing the film side, and also a chance of getting one's fingers over the sensitive surface, for sometimes the plate is face up, sometimes face down, in the box.

A much better arrangement would be to have the plates all film down, then there can be no mistake; and, further, it is possible to lift them out by the pneumatic holder—by far the best plan.

For separating, the most convenient arrangement would be a continuous strip of pure tissue paper zigzagged between the plates, so that by lifting the free end the plates come up one at a time, and all film down. In this

connexion the suggestion of the Editor, *re* gummed strips, might be worked in.

Then for the boxes. Here I must confess to a decided partiality for the method adopted by Thomas; as all may not know it, here it is:—A strip of orange paper, first of all, of equal width with the plates, completely encloses them in the long direction. This parcel is placed in an open box, and the whole then wrapped in strong, black, glazed paper. This package, now presumably light-tight, is next slipped into an envelope box open at one end, and this again, open end first, into another envelope. Thus it is a moral impossibility for any light to strike through the three cases to the plates. I should add, however, that the black wrapping above-mentioned has lately been improved upon (?) by the substitution of a semi-transparent paper of a non-actinic colour for the black opaque one previously used.

If there is any better packing in the market I would be glad to hear of it, as I have only tried half a dozen or so different makes. If there is not, then the above plan should be more generally adopted.

I trust that others who have suffered loss of time, trouble, and money through badly or irrationally packed plates will ventilate their opinions for the benefit of photographers in general and travellers in particular.—I am, yours, &c.,
WILFRED L. SPENCE.

Manchester, August 19.

Exchange Column.

*. No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Wanted, a camera and lens in exchange for a quantity of plates, dishes, printing frames, &c.—Address, CHARLES JOHNSON, Wincanton, Bath.

Exchange half-plate Meritoin with three double backs, lens, and tripod, for quarter-plate set.—Address, MERITOIRE, Rock-cottage, Instow, North Devon.

Brocaded silk studio curtain, eleven feet by five feet, and porcelain lip tray, 17×14, in exchange for Victoria camera and nine lenses, dark slide, &c.—Address, H. T. AULT, 15, Warfe-street, Newcastle, Staffordshire.

I will exchange boat, oar, and water-piece, studio table, 12×10 camera, and rustic bridge, for interior backgrounds, posing chair, or other outdoor accessories.—Address, F. C. D. HURN, 10, Cowl-street, Shepton Mallet.

Wanted, whole-plate brushier, half-plate portrait lens, and studio accessories, in exchange for a quantity of developing dishes, retouching desks, and enlarging cameras.—Address, B. P. C., 71, Montague-street, Blackburn.

For exchange, exterior background, brushier, ten-inch roller, sociable tricycle, and bassoon; wanted, exterior and interior backgrounds, and cabinet and carte enamelling presses (Marion's preferred). Photographs exchanged.—Address, J. H. G., 36, Commercial-street, Brighouse.

Exchange balustrade, pedestal, and vase for a different set. A Grubb's 1½ portrait lens, Voigtlander's ditto, three and a quarter inches diameter, ten inches focus, and 12×7 hot roller offered as exchanges; want a good upholstered armchair or other interior accessories.—Address, ATKINSON, Photographer, Workington.

Answers to Correspondents

*. Communications relating to Advertisements and general business affairs must be addressed to "H. GREENWOOD & Co.," 2, York-street, Covent Garden, London, W.C.

All matters for the text portion of this JOURNAL, including queries for "Answers" and "Exchanges," must be addressed to "THE EDITOR," 2, York-street, Covent Garden, London, W.C. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.

PHOTOGRAPHS REGISTERED:—

W. K. B. (Tokio).—New and excellent model selected. Despatched ere this meets your eye. Will write.

F. E. S. (Dorking).—When you are in London give us a call, and we will give you the required information.

A. Z.—The new film is not yet in the market, we believe. It will be, we are informed, in a very short time.

YORKS.—The "peculiar marks" are what is known as "pitting." We have seen other examples on the same brand of plates lately.

S. CRESWICK.—All things being equal, one lens will be as quick as the other; that is, if both be used with an aperture of, say, *f*/16, there will be no difference in their rapidity.

D. McINTIRE.—There is no recognised system of book-keeping amongst photographers. Almost every one has a system of his own, which he has adapted to suit his requirements.

W. THOMAS.—The copyright in Hogarth's works has long since expired, consequently you can make lantern slides from them. Not so, however, with the other works named; for these you will have to obtain permission, and we are very doubtful if it will be accorded.

E. WORDERSON.—The fault must be yours. We have never heard of any one else failing with the process, which certainly does all that is claimed for it. We ourselves never had a failure with it, nor should we expect to have. Try again, and follow implicitly the instructions as they are given.

J. W. CARTER.—Obtain any elementary work on optics. In this column we cannot enter into such things as the construction of optical toys.

WADEEN.—You must not imagine that because you have been granted a patent that it is of necessity a valid one. If any one has used publicly or sold, as you say is asserted, a similar contrivance prior to your patent it will invalidate it. Few patents can be considered really valid until they have been litigated.

A. H. C.—1. The camera sketched as No. 2 is the more portable, but we prefer the square bellows, as it permits of using a pair of lenses for stereoscopic work while the conical bellows does not. Furthermore, the No. 2 form is not so convenient when using a wide-angle lens.—2. The longer-focus lens will cover the plate the best with a large diaphragm, but it will not include quite so wide an angle.—3. The paper named does not require any special treatment from other bromide papers. Employ the developer recommended by the makers, the formula for which is sent out with each parcel of paper.

A. BLACKLOCK writes: "I recently ordered some ready-sensitised paper from a London firm, and upon opening the parcel I found it had a most disgusting odour. I have never had ready-sensitised paper before, as I have always used — paper and sensitised it myself, and that never has any smell whatever. I have made a few prints on the paper, and it appears to work all right; but do you think that prints made on such paper are permanent?"—Opinions on this subject are somewhat divided, but paper of this description is largely used. We have in our collection some prints on similar paper which show no signs of fading, although they are a dozen or more years old.

S. A. H. writes: "It seems to me that the only plan for securing a perfectly flat surface with films is to expose behind a glass plate. Is there any real objection to doing this? I believe that in the old calotype days cameras were frequently made with the focus arranged specially for this mode of exposure. When the gelatine film has been cleaned off from the celluloid (Carbutt's make) I find this substance most useful instead of tissue paper for printing, and if it could be kept flat would be a most excellent substitute for the usual ground glass for focussing."—In reply: There is only this objection, that there will be a very slight loss of light by reflection from the covering glass. The old calotypists were very particular in selecting glass free from colour and blemish.

Z. BLUNT asks: "Could you kindly inform me, in your 'Answers to Correspondents,' the following? I am a printer and toner; I have a toning bath made of acetate of soda and gold, in all to two gallons of water; now, I have on an average one and a half quires of paper to tone a week, and make two or three tonings of it; how should I keep this in good working order? I am going to make up a new bath, and want it to be good; how much acetate should I put in to start with, and how often should I add more, and in what quantities (purple tones required)?"—Thirty grams of acetate of soda should be employed for each grain of chloride of gold. As the bath becomes exhausted more gold must be added, in the proportion of one grain for each sheet of paper toned. Occasionally a little more acetate of soda must be added.

F. J. is a photographer in a country town, and has lately taken to supplying photographic chemicals, plates, and paper. This, it appears, has given annoyance to a chemist and druggist close by, who has threatened proceedings against him if he sells things of a poisonous character, such as bichloride of mercury, cyanide of potassium, &c. Our correspondent asks if he can do any such thing; if so, where he can obtain a license to sell the chemicals, and what is the cost.—Certain poisons named in the schedules of the Poisons Act, amongst which are the ones referred to, can only be legally sold by properly qualified pharmaceutical chemists, and by them only under certain restrictions. Any one else vending the poisons is liable to very heavy penalties. There is no license which will exempt the vendor from the penalties when he is not a qualified pharmaceutical chemist.

E. D. writes as follows: "I have lately experienced great difficulty with my toning. I use the borax bath—one and a half drachms of borax, two to three grains of gold, and fifteen ounces of water. I use this bath warm, and put in about six prints (whole-plate) at a time, keeping them well on the move. Lately, quite half the prints in a batch go as the enclosed. The curious thing is the straight stains across the prints at different angles. The toning and fixing dishes I use are not big enough for the prints to lie anything but square, so cannot account for these marks appearing as they do. During my last toning I kept one print in a long time, as it had been over printed, and eventually took it out and hung it up to dry without fixing or washing. This print had no stains on it, so I conclude they must come after leaving the toning bath. Would they be likely to appear during washing, between the toning and fixing? I use plenty of hypo, and do not think the prints ever stick together whilst toning. The remedy for the above annoyance would oblige."—The stains are caused by the prints being contaminated with hyposulphite of soda before they are put into the fixing bath. Probably the dishes in which they are washed after they are taken from the toning solution are not perfectly clean. Care and cleanliness will avoid the trouble in future. The change was made the first week in April.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1530. VOL. XXXVI.—AUGUST 30, 1889.

SOLUTIONS OF THE CAUSTIC ALKALIES.

A WEEK or two since we mentioned the uncertainty that may arise from the deterioration of solutions of sodium and potassium hydrate, now so commonly employed in place of the carbonates in development, and pointed out that this may arise from absorption by the solutions of the carbonic acid always present in the atmosphere. The affinity of such solutions for carbonic acid is so powerful that potassium hydrate, or a mixture of potassium and calcium hydrates, is employed by chemists in all delicate analytical operations where a current of air is to be employed for freeing it from all traces of carbonic acid. Our contributor "Junius" has pointed out a useful method of remedying or preventing this deterioration, based on the circumstance that calcium hydrate has a still more powerful affinity than either potash or soda for carbonic acid, and when brought into contact with the carbonates of those bases, deprives them of their acid and leaves them in the free or caustic state.

It has appeared to us probable that the plan thus mentioned by "Junius" may prove useful in many instances beyond those where it is employed for remedial or preventive purposes. The hydrates of sodium and potassium are not everywhere obtainable of anything like reliable quality; almost any country chemist, it is true, can supply "liquor potassæ," the pharmaceutical solution of potassium hydrate, but even if it be comparatively freshly prepared and free from carbonate, it is not an easy matter to the ordinary photographer to convert it to terms of a practical formula. But the carbonate of potash, and especially of soda, can be obtained anywhere, and of fairly reliable value; and starting with these as a basis, the photographer never need be at a loss to supply himself with a trustworthy solution of the hydrate. We therefore propose to give simple directions for operating with these substances, and the relative quantities to be employed.

Carbonate of soda in crystals, or ordinary washing soda, as most commonly employed, consists of the anhydrous salt, together with ten equivalents of water of crystallisation, or 106 parts of carbonate of soda and 180 parts of water, and the proportion of sodium hydrate present is 80 parts. Therefore, 286 parts of washing soda, or 106 parts of the anhydrous salt, are required to produce 80 parts of the hydrate; or, in approximate figures, $3\frac{1}{2}$ parts of soda crystals contain 1 part of caustic soda.

With these figures to work upon, let us proceed to make up

the formula for use with hydroquinone known as Thomas's. This consists of—

Sodium hydrate	160 grains.
Water	20 ounces.

We therefore take three and a half times 160 grains, or 560 grains of clean crystals of washing soda; in selecting these, the large, clear crystals should be chosen, as the white, powdery portions which have effloresced or lost a portion of their water of crystallisation contain a relatively larger proportion of alkali, and will therefore vitiate the calculation. One ounce and a quarter of the crystals will represent the quantity required, only short about thirty grains of the full theoretical quantity, and for the sake of clearness and "round numbers" may be taken as sufficiently near the mark. This is to be dissolved in half a pint of water, preferably hot.

We next turn to the calcium hydrate, which, as pointed out by "Junius," must be freshly slaked or hydrated; we therefore start with the "quick" lime. Comparing the equivalents, we shall find that 56 parts of quicklime are equal in combining power to 80 parts of caustic soda, or seven-tenths of the weight; and that therefore for the above quantity of material we require 112 grains of lime. But as an excess of the lime not only does no harm, but is rather desirable, we may weigh out, say, half an ounce, which is nearly double the theoretical proportion. This is slaked by pouring upon it in any suitable vessel, *not* of glass, sufficient water to cause it to swell up and crumble, giving off at the same time great heat and considerable quantities of steam. When the action has ceased and all is quiescent, the hydrate is beaten into a smooth paste and the solution of washing soda mixed with it and boiled for about ten minutes in a porcelain evaporating basin or an enamelled iron saucepan. It is then allowed to cool down, the volume made up to twenty ounces and allowed to settle.

There is no necessity to remove the sediment, which, as mentioned by "Junius," settles—the calcium hydrate being in excess—to keep the solution in good condition. If a portion be required in a hurry, or before it has had time to clear, it must be filtered through "glass wool," as even in weak solution the caustic alkalies act powerfully on filter paper.

To make a solution of potassium hydrate of equal alkalinity, 276 grains of *dry* carbonate of potash, or five drachms, will be required. If the pure anhydrous carbonate be obtained, it will be advisable to dry it by spreading it on a plate in a hot oven

for an hour or so. If, however, the crude carbonate of the shops be in question, the drying is a matter of the utmost necessity, as owing to its deliquescent nature, the quantity of water present is always large.

The remaining operations, as well as the proportion of calcium oxide to be used, are identical with those already given.

NEGLECTED PROCESSES.—LAMBERTYPE— CONTRETYPE.

The Lambertype is often confounded, especially on the other side of the Atlantic, with the chromotype process, while, as a matter of fact, it bears no relation to it whatever. Our older readers, particularly those who have paid heavy fees for licenses to work them, will not require reminding that M. Lambert, when he was here some twelve or fourteen years ago, introduced three distinct processes—namely, the Chromotype, Lambertype, and the Contretype. They were, however, all based upon the carbon process. The chromotype, perhaps the best known of them all, was treated upon a fortnight back; the others will be referred to here.

The Lambertype process proper is a method of producing enlargements in carbon—introducing or changing backgrounds, printing in portions from second negatives, &c.—in such a manner that no hand work is required on the ultimate print. The process, we believe, was never carried out in the manner its originator intended, owing to a tissue suitable for making the transparencies not being forthcoming. The tissue desired was one in which the colouring matter, preferably a red, was in a somewhat coarse state of division, so that in the enlarged negative a manifest grain or stipple was obtained. By this means much labour might be saved in the finishing and a more artistic result secured.

The main feature of the Lambertype process was the method of working up or retouching the enlarged negative. In a word, it consisted in expending the whole of the work on the negative instead of on each individual print. We well remember, at one of the Photographic Society's Exhibitions, some examples were shown, which were, so far as the prints were concerned, absolutely untouched. In some of these, not only had the backgrounds been changed, but also portions of the dress as well, still no joins were perceptible. Some of those examples were taken from small paper prints, yet no one would have suspected that they were not from original negatives, but for the intimation that that effect on the mounts.

The process is, or rather was, worked as follows:—An enlarged negative was made from a carbon transparency in the ordinary manner. In the development, however, it was kept very thin, so thin indeed that, in its then state, it would be far too feeble to yield a presentable print. This negative, after varnishing, was covered on either side with a thin translucent paper. This, to an extent, increased its density, but, of course, uniformly all over alike. The negative was then placed on a retouching easel, back upwards, and the lights and half tones strengthened roughly with a coarse stump charged with plumbago until sufficient printing vigour was obtained. Then the negative was turned over and the finer details strengthened, and the high lights put in with a fine stump or with a lead pencil, as the case might be. Sometimes, if still further printing vigour was required, it was obtained by cutting away portions of the paper on the back side of the negative corresponding with the deepest shadows.

The Lambertype process of finishing may, in fact, be termed

a mechanical method of intensifying the negative, and on those portions alone where it was necessary. It is scarcely necessary to explain that a certain amount of skill and artistic ability is requisite to execute the work satisfactorily, though not more than is possessed by every skilful retoucher.

The method of changing the background or printing in portions from a second negative was unique. The outline of the subject desired to be altered was traced on the paper at the back of the negative with a fine pencil. The negative was then placed closely into one of the angles of the printing frame, and the tissue—for this method was only designed for carbon printing—was placed upon it. This was also pressed closely into the same angle and the frame closed. The outline was then gone over with an opaque oil colour mixed with a non-drying oil on the glass of the printing frame—which, by the way, was rather thinner than usual—for a quarter of an inch or so, keeping very slightly without the pencil tracing of the subject. A rough paper mask was then placed on the glass to cover up the remaining portions required to be blocked out. After printing, the paint and mask were removed and the outline painted over afresh, this time keeping a little within the pencil line. The negative was then removed from the frame and the second one introduced. The tissue being again closely pressed into the same angle of the frame secured accurate registration. A rough paper mask, to protect the portions already printed, was laid on as before, and the second printing then completed.

The principle of this method of masking is this:—The light creeps under the painted lines and paper mask, so that the two printing are, as it were, vignettted the one into the other, hence no juncture is perceptible.

Frequently, when the enlargement was from a paper print, M. Lambert partially printed the picture—say to the extent of three-fourths—with the tissue in contact with the negative; then a thin sheet of glass was interposed, and the printing completed through that. By this dodge the granularity due to the original became imperceptible. It was by this method of working that M. Lambert's enlargements from paper prints so closely resembled those from original negatives. The Lambertype process might well be described as a series of very ingenious and useful practical dodges.

The Contretype process, which, by the way, never received much attention, was a simple one for reproducing negatives by the carbon process. But in this case the transparency was made in a tissue of a red colour, and the pigment therein was so proportioned that a somewhat high relief was obtained, even from feeble negatives. This transparency could then be easily intensified with the permanganate of potash. This is not the case with a transparency from a weak negative, printed in a tissue highly charged with opaque pigment. From the intensified transparency the negative was printed either in the same or any other tissue. This, in turn, could afterwards be intensified or not, as circumstances required.

IN a footnote last week we then quite misapprehended the position of the Council of the Convention in regard to the publication of the papers which were contributed. On entering the Council Room on Tuesday evening we were informed by a fellow-member that the distribution of printed slips of the papers to those in the Convention, the press included, might be considered as a rescinding of the previous determination to withhold publication till after the close, and this we considered justification for giving two papers in our last. We only learnt after the JOURNAL was at press that no such rescinding

of the original intention had been made, and we immediately saw that, however undesigned, we could be open to the charge of not having kept faith, the photographic press not being in the same category in this respect as the general press. We are sorry for this misapprehension, but it was entirely unintentional.

Among the many causes of discrepant results in photographic operations, that of impurity in chemicals has been frequently dwelt upon, though, within our own knowledge, it has often been the cause of serious trouble, if not of actual loss. It is, however, not only photographers who suffer this way, for we note quite recently in the published account of an investigation by Mr. D. J. Carnegie, M.A., upon certain iron and iodine reactions, that his own experiments and, in all probability, those of his predecessors on the same ground, were at first vitiated by the presence of a foreign substance in a presumably pure sample of the salt he was using, a salt, moreover, of constant employment in photography—iodide of potassium.

THE salt in question is of such importance in photography that we consider our readers will be interested in the portion of Mr. Carnegie's remarks bearing upon it, the more so as it may have a bearing upon the condition of bromides as well as iodides. He states that after making numerous experiments, whose results did not satisfy him, he subsequently found that their cause to be the "presence of an impurity in the 'puriss' potassium iodide used. It is well-known that commercial KI frequently contains KOH and K_2CO_3 ; but this impurity is apparently not confined to the commercial article, for samples of the purest KI supplied by two of the best known British firms contained respectively 2.3 per cent. and 1.0 per cent. Now the extreme importance of this impurity in iodometry has never, I think, been sufficiently emphasised; the text-books, in the fervour of their warnings with respect to the evils arising from the presence of iodate in potassium iodide, have completely overlooked quite as formidable an impurity. Both KOH and K_2CO_3 , 'fix' free iodine, and it therefore follows that all iodometric estimations (even the simple standardisation of thiosulphate against pure iodine dissolved in KI), unless special precautions have been taken to the contrary, are vitiated in varying degree by the alkalinity of the impure KI."

THESE remarks will also assist in clearing the ground to describe a new method of testing volumetrically for silver. It would, perhaps, be difficult to find a simpler process than the ordinary chloride of sodium precipitation, but as it is never advisable to be tied down to a particular formula or mode of operation, it will be interesting to note this new method. It is founded on the reaction between starch and iodine, and is just as applicable to silver as to mercury. M. Carnot writes:—"1. First take the case of mercury, which must be in the mercuric state. The solution diluted with water to 100 or 150 c.c. is put in a beaker with about 10 c.c. of nitric acid and a little clear starch paste. Then a decinormal solution of potassium iodide (10.61 grammes of the pure salt per litre) is dropped in from a burette, stirring continually with a glass rod. Each drop produces at first a yellow precipitate, which quickly dissolves on stirring; then the precipitate turns gradually to red. At the moment when the mercury is entirely converted into the insoluble iodide the least excess of the reagent liberates iodine, which at once colours the starch. Before the end of the operation we perceive, at the place where the drops of the reagent fall, blue and afterwards brown spots, which disappear at first rapidly, then they form trains of a dark brown in the midst of the red liquid, and finally give it a general brownish tint. The exact moment must be seized when a permanent change of colour is observed. If this is ever so little overstepped, the liquid, when left to itself, remains of a blue colour after the subsidence of the red precipitate. When the quantity of mercury to be determined has been approximately found by a first operation, it is advantageous to add at once almost the total quantity of the reagent necessary, and to add the starch and the nitric acid afterwards. The remainder of the standard reagent is then added drop by drop until the reaction is completed. 2. Silver is determined in the same manner as mercury.

If the substance in question is of unknown composition, we make first an approximate determination. According to this first datum we calculate the approximate weight of the silver contained in the portion taken for analysis, we dissolve it in nitric acid, dilute it to 100 c.c., introduce the calculated quantity of the decinormal potassium iodide, and stir briskly, so as to collect the pale yellow precipitate of silver iodide in the form of dense clots. We decant the liquid along with a little washing water into a beaker, add some c.c. of starch paste, and about 10 c.c. of nitric acid slightly nitrous. If at this moment the liquid becomes blue, it is exactly decolourised by means of a centinormal solution of silver nitrate (1.7 gramme nitrate per litre). If it is not coloured blue we pour in at first potassium iodide until the permanent blue tint appears, which is then removed again by means of the centinormal silver solution. In this manner the author has obtained results accurate to 0.1 or 0.2 milligramme when operating upon known quantities of silver from 1 to 200 milligrammes."

In the House of Commons last week, on the report of supply on the British Museum Vote, some of the members appeared to be a little "mixed" with regard to the photography practised there. They seemed to think that some of the "Parnell letters" were copied by the official photographer, and with the apparatus belonging to the department. As a matter of fact, there is no official photographer at all attached to the Museum, neither does the Museum possess any photographic apparatus whatever. There is a photographic studio and dark rooms which are at the disposal of those desiring to make copies of the prints, manuscripts, &c., but they have to bring their own apparatus. When the authorities require any photographs taken for the Museum, they have to invoke extraneous aid. Of course, permission has to be obtained to photograph anything in the Museum, but this is readily accorded by the authorities, and, when it is obtained, every facility and assistance are afforded for securing the best possible result. A letter addressed to the Trustees meets with prompt attention.

At the National Gallery there is no such convenience. Permission is easily obtained to copy any of the pictures, but there is no studio to do the work in, and they must not be taken out of the building. An exception was made to this regulation a few years ago to Messrs. Braun, of Dornach. They were allowed to put up a studio outside the building, in which they worked for several months. If such exceptional privileges as these are ever again accorded, it is to be hoped that the Trustees will stipulate that copies of the different works will be supplied to art students at a cheaper rate than they are at present.

In the Civil Service estimates, some thirteen hundred pounds were voted for the National Portrait Gallery. Up to the present time this department has not recognised photography at all. In the projected new building which is to contain the pictures it is to be hoped that a certain portion will be set apart for photographs. There are many persons who have distinguished themselves in the different walks of life, and whose counterfeit presentments their country would like to possess, but no oil painting of them are in existence, though there may be excellent photographs of them. Photographs can be produced as permanent as oil paintings, and generally they are far better as portraits. In a national collection of portraits, works of art, one would imagine, should be a secondary consideration, and a truthful likeness of the individual the primary one. We hope that the many amateur photographers who now have seats in Parliament will look after this subject.

SOME discussion arose on the vote for the National Gallery last week. When the exorbitant sum was paid for a couple of pictures some little time back, it was stated that no more money was to be expended in this direction for several years. It was, however, explained that when the opportunity occurred for securing an important work at a moderate price it was embraced. This is wise. Our collection of pictures is by no means large, considering what is to be seen in the galleries of other countries.

FILMS IN THE CHANGING BOX.

WITH the introduction of films instead of glass for negative purposes, it might not have been unreasonable to expect a greater gain in the matter of portability and compactness in the apparatus for carrying them than seems at present possible. The roll holder, it is true, carries a large number of exposures in a tolerably compact form, but despite the undoubted ingenuity and almost perfection of mechanism of several of those in the market, there is in many directions a prejudice against them and in favour of employing the cut sizes.

The thickness of the glass plates being dispensed with, it is commonly said that the dark slides can be made much thinner and lighter, which is the case so far, at least, as the actual thickness of the glass is concerned, but no farther; and when we come to consider the size of a double slide so reduced to the utmost extent, we find that half an inch is the minimum measurement we can attain, as cameras are at present constructed, a thickness which seems out of all proportion in the camera for a couple of films that do not measure together one-fiftieth of an inch. The future of films seems, therefore, to be connected either with roll holders or some form of storage carrier in which a large number of cut sheets may be packed and exposed by means of a separate exposing slide, or otherwise, instead of carrying them separately.

But before the era arrives of special apparatus, there will be a large section of the users of films who will do their best to employ to the greatest advantage their existing apparatus, and for them have been already provided a large variety of film carriers for use in the ordinary slides, but as yet no provision has been made for utilising existing apparatus of the changing-box kind. And yet Hare's changing box may be adapted in an extremely simple manner, not only for use with single film carriers, in which case the advantage gained ends with the saving of the weight of the glass, but also with double carriers with a practical gain of double the number of exposures in the same space, and with only the additional weight of the extra films.

The plan I devised, partly for my own use, and which I have for some few weeks had in practical work, consists briefly of an adapter by means of which the dark slide may be applied to the changing box in the reverse way as well as in the ordinary manner, so that both sides of a double film holder may be exposed in succession. I have shown a rough, workable model of the appliance to Mr. Hare, who is prepared to adapt it to any instrument that may be sent to him.

It adds little to the weight to be carried, not more than three or four ounces for a $7\frac{1}{2} \times 5$ box, does not unfit the changing box for use with glass, and is quite inexpensive. It consists simply of a piece of wood, a quarter or three-eighths of an inch in thickness, an inch and a half wide, and the length of the shorter dimension of the dark slide. This is pierced with a slot through which the plate passes, and on one side is screwed a brass plate also carrying a similar slot, and which is a facsimile of the slot plate at the end of the dark slide. On the other side are fixed two strips or guides, identical with those on the lid of the changing box, but placed in the reverse position. When the slide is run home into these guides, the slot plate of the adapter is applied to the changing box in the ordinary manner, and opens the communication between the box and the slide, but with the latter in the opposite position to the ordinary one, that is to say, with the shutter or exposure side in the contrary direction.

I had intended giving a drawing of the parts, but really there is no necessity, since a simple glance at the brasswork on any existing instrument will explain everything. This has simply to be duplicated, and a thin piece of mahogany "sandwiched" in between and the thing is complete. Probably Mr. Hare will improve on my idea in its details, but that constitutes the broad principle.

Although the contrivance is so simple, it will require some little care in use in order to avoid accident, as I shall now point out. Those who are familiar with Hare's changing box will be aware that the act of sliding the dark slide on to the box opens the slot in the lid through which the plates pass, the brass plate which closes the opening remaining unmoved until the aperture is covered by the slide, the last half inch or so of the push home effecting the object. For this reason the adapter should remain permanently attached to the slide, if that were possible, because if pushed home into the jaws of the box, when unattached to the slide, the contents of the box would be

submitted to the free action of light. The adapter, however, cannot remain on the slide, as it would prevent the insertion of the latter in the camera, hence it must be removed before each exposure.

It may, however, remain attached to the box itself, at least during the time that the reverse sides of the carriers are being exposed, if proper precautions be observed, and here it is that the necessity for care arises. If inserted into the jaws of the box about two-thirds or three-quarters of the full distance, or so far as to still leave a portion of the opening in the woodwork visible, the brass slide remains closed, and in this state the plates are as "safe" as at any time. The slide may now be pushed on to the adapter from the opposite direction, and when in position the adapter itself is pushed home and opens communication. After taking out a plate before removing the slide, the adapter must be first pushed partly off so as to expose the aperture, when the box will be closed and the slide may then be detached. This must be imperatively borne in mind, and perhaps some arrangement is desirable to prevent the removal of the slide before this closing of the box has taken place.

In practice, therefore, it will be most convenient to expose, first of all, what I will call the front sides of the film carriers, that is to say, to make twelve exposures without using the adapter. Then, placing the adapter in position, proceed to make the twelve additional exposures of the reverse sides, carefully observing the precautions I have mentioned, when the trouble arising from the use of the adapter will be reduced to a minimum. No difficulty need be experienced in the identification of the different exposures, because the films always occupy the same position in the box, and the front film of No. 1 carrier will be No. 1 the reverse side, No. 13 exposure, and so on.

I mentioned in the early part of my description that the adaptation of the changing box to film purposes does not unfit it for use with glass, but clearly when using double carriers the fixed springs in the slide must be temporarily removed, or they would seriously damage the film, besides interfering, perhaps, with the entry of the light carriers. In removing the springs it is necessary to see that the screw holes do not let in light; if they do, the remedy is obvious.

The substitution of suitable springs to keep the thin carriers in position is the most awkward part of the business, owing to the construction of the slide in which the plate or carrier slides in a groove, and not simply a rebate, and consequently it is difficult to get at the edges of the carrier where alone the springs must bear. I have got over the difficulty by screwing on to each corner of the hinged pressure-back a short but comparatively stiff spring reaching into the groove, and so shaped that when the back is closed the springs bear forcibly on the corners of the carrier, but come clean away when the catch of the back is removed to open the slide. My arrangement works perfectly, but it is in these minor details most probably that Mr. Hare will be able to make improvements.

This arrangement, let it be understood, is simply a makeshift, but a thoroughly practical one to be used in connexion with existing apparatus. If the changing box were specially constructed for films, it is probable that at least three dozen exposures could be carried in the same space as one dozen plates, and the full box would then be lighter than with twelve glass exposures.

W. B. BOLTON.

ECHOES.

It is refreshing to have one's memory jogged by such articles as those on *Neglected Processes*—processes in which, at some period, you have had an interest of some sort, but which have long since been dropped and forgotten. The editorial on the chromotype process a week or two since recalled to my mind the perfect *furore* it caused in professional circles at the time of its introduction, and I shall not easily forget the deep impression it made on my mind to watch the easy manner in which M. Lambert produced results that put into the shade anything that had previously been obtained by the carbon process. I never, however, worked the process, except experimentally, though I still look with feelings of the greatest delight upon the few specimens I possess.

As to the reasons why the process, now that all restrictions are removed, is not more generally worked, I think those mentioned in

the leader referred to may be set on one side, with the exception of the final suggestion that it is "more troublesome" than silver. The patent rights no longer exist, the alleged fugitiveness was not a necessary characteristic, if I may judge from samples in my possession fourteen or fifteen years old, and the extra cost might with equal propriety be urged against platinotype; but that is worked. The fact is, the photographer of to-day does not like trouble, and so he will not work any form of the carbon process.

In addition to the fact that each individual print has to be submitted to the careful process of development—and, consequently, to treat practically singly a large number of prints is beyond the power of most amateurs—it is to be remembered that the mere exposure is much more of a "leap in the dark" than that of a negative; besides the fact that the progress of the image cannot be watched, even if it be accurately timed by an actinometer it must be developed within a stated time, otherwise the so-called "continuating action" steps in to upset everything. This and similar matters tend, in my opinion, more than anything else, to confine the practice of the process to large, well-disciplined establishments.

By the way, I do not think it is quite accurate to say that the late Jabez Hughes ever "entirely abolished" silver printing. I think I remember his telling me that he still used silver for certain purposes, though I forget what; and I certainly have a picture of his—a group consisting of Her Majesty and upwards of twenty of her children and grandchildren—taken, I suppose, about nine years ago, and given to me by him at the time, which, if not an albumenised silver print, is more like one than anything in the shape of carbon I ever saw.

Reverting to the remark I have just made with regard to the modern amateur's dislike of trouble, I cannot help feeling somewhat with the "amateur" whose opinion is quoted in a leaderette on the question of whether the introduction of gelatine plates has been an advantage to photography or not. At the same time I cannot shut my eyes to the editorial view of the question. It is no doubt galling to the "old hand" to find himself reduced to level terms with the tyro of a month, but it is, after all, a selfish feeling that makes him begrudge the novice his pleasure. He, the old hand, possesses the same advantages as the beginner *plus* the very important one of long experience; if his appetite for such pleasure has become a little dulled with age, let it not make him envious. The beginner of to-day is, perhaps, every whit as enthusiastic as he himself was a quarter of a century ago, and it is his good fortune rather than his fault that he has better means at his command.

I remember an old friend, an amateur of many years' standing, who had worked wet and dry processes with the greatest assiduity, but with very little artistic result until the gelatine process came in. It was his practice to try every new process, and of course he went in for Kennett's pellicle as soon as it was in the market, with the result that he turned out, as it was said at the time, his first pictures. He was one of the earliest enthusiasts in gelatine, and is still occasionally quoted as an authority in the earlier development of the process. So no doubt, with many others, the new process made all the difference between unsuccessful and successful plodding.

Apocryph of the liability of solutions of the caustic alkalies to lose their energy by absorption of carbonic acid, I may say that I recently had a very strong proof. Finding my development much more protracted than it had been earlier in the season, though using the same plates, I first suspected my stock solution of hydroquinone, so made up a fresh lot, with no better results. I then examined the alkali, and found what should have been "caustic" to consist very largely of carbonate. Since then I have adopted a plan which I think will prove useful to others.

First as regards a test, if a solution be suspected. Drop into a portion of it a small quantity of any strong acid—nitric, sulphuric, citric, acetic, or anything that may be handy, except sulphurous; if the mixture effervesces carbonate is present, and the quantity may be judged by the strength of the effervescence. Even when newly made a solution of sodium or potassium hydrate will contain some, possibly a good deal of carbonate, as the "sticks" themselves absorb carbonic acid. By adopting my plan the carbonic acid may be eliminated and the solution kept constantly in a state of free activity.

Procure some oxide of calcium or quicklime and "slake" it by pouring a little water on to it in a saucer; when all action has ceased,

break it down with a spatula and transfer it to the bottle containing the soda or potash solution and shake up well. The carbonic acid will leave the soda or potash and go to the lime, which thus restores the soluble alkali to its caustic condition, and constantly keeps it so. The lime should be freshly slaked as I have described, otherwise that will have been reduced in all probability to carbonate. In my practice I keep a "Winchester" of stock solution of alkali, into which the calcium hydrate is put; from this I fill up from time to time a smaller bottle, from which I use, and at the time of each such filling I shake up the "stock," bringing the lime and solution well into contact, and the sediment will have settled down by the time I want it again.

This was an old device of twenty odd years ago for "freshening up" the carbonate of ammonia solution then employed, or for giving it greater energy in cases of under exposure. This it did by neutralising the restraining effect of the carbonic acid and converting the solution into one of liquid or "caustic" ammonia.

Mr. J. R. Swain, in a paper extracted from the *St. Louis Photographer*, gives a, to me, new remedy for blisters on albumenised paper. This consists in immersing the prints, after toning, in a five per cent. solution of acetic acid, and it is stated to be an infallible preventive, acting by "toughening" the albumen. It may be, and probably is, effective, though I do not see the need of further toughening the albumen, which in blister cases is usually tough enough. But I am surprised no further stress is laid on the necessity for washing before fixing beyond that contained in the words "washed once or twice and fixed as usual." Surely a print containing free acetic acid is scarcely in proper condition to go into the fixing bath after the "washing once or twice" it is likely to get at the hands of the ordinary printer's assistant, unless his attention is strongly drawn to the fact that acetic acid, or any acid, precipitates sulphur from the hypo.

The *Scientific American* gives a remedy for the yellow stain in gelatine negatives caused by imperfect fixation, and I am glad to see that the editor only commits himself to saying he has "thought of, but not tried it." Perhaps when he has tried it he will tell us he has done so, but no longer *thinks* anything of it. The stain so produced is about the most permanent thing I know of in connexion with silver deposits, being, I suppose, honest sulphide of silver. But even if bichloride of mercury would touch it I don't quite see how matters would be improved—but rather the reverse—by converting it into a brown or black—scarcely bluish fog.

I note that attention was called at the London and Provincial Association to the fact that eikonogen and sulphite of soda will develop the image without any alkali. My first experiment with the new developer rather surprised me. Before making up my stock solution I was anxious to try the new agent, so dissolved six grains in water without any sulphite. This was applied to the plate, which had had a "normal" exposure, and the image began to appear so rapidly that, having read of the great energy of eikonogen, I flew to the bromide bottle, and after copious additions of a sixty-grain solution I managed to curb the "mad haste" of the solution, and, finally, completed a fairly good negative, only wanting a little in vigour. It was not until I had fixed it that I discovered I had used no alkali at all! Surely if eikonogen *plus* bromide will develop, eikonogen *plus* sulphite ought to do so handsomely.

Mr. Latimer, in exhibiting to the members of the Birkenhead Photographic Association a half-plate camera with an adapter for taking a whole plate, is reported to have said that he only uses his half-plate single lens for all purposes, and finds that by stopping it down it answers perfectly for whole-plate pictures. While I do not for one moment doubt the possibility of using a half-plate lens for the purpose mentioned, under certain conditions, I cannot help thinking there is something peculiar about Mr. Latimer's lens. If it has its stop properly placed to cover a half-plate, it is, I should think, scarcely in the right place to be reduced sufficiently to make the lens cover twice the area. Then, again, if the lens is of such a focus as to give good all-round results on a half-plate, it becomes a decidedly wide-angle lens for whole-plate purposes—a wide-angle lens, moreover, very ill-suited for wide-angle purposes generally, but for architecture and interiors especially. On the whole, such makeshifts are not to be applauded.

Poor "parent Society!" what new *lapses* have you committed that Dr. Edwards should propose to found a Royal Photographie Society, not only over your head, but without consulting you? JUNIUS.

THE CONVENTION.

SECOND NOTICE.

Wednesday, 21st.

TAKING the papers in order, the two following, respectively by Mr. Haddon and Mr. Dunmore, were read on Wednesday:—

DESENSITISING AND RESENSITISING ALBUMENISED PAPER.

By A. HADDON, M.P.S.L., *Demonstrator in Physics, Royal Naval College, Greenwich, S.E.*

I MUST at the very outset apologise for appearing before you with such a paper as I have in hand, but the fault is not mine; the responsibility rests rather with others than myself. On the 24th of July of this year I made a few remarks on this subject before the London and Provincial Photographic Association, the task having been kindly thrust on me by our worthy friend and past President, Mr. J. Traill Taylor, and on resuming my seat after the few words I was told by him that I should be expected to read a paper before you on this same subject this evening.

The object of the few experiments I have been making is to ascertain whether it is possible to thoroughly desensitise paper which has once been made sensitive to light, and again resensitise it so as to obtain passable prints from such paper. Had I made my experiments first I should not, most probably, have chosen the title that appears at the top, because as far as I have gone none of the ordinary reagents that I have employed deprive the paper entirely of its sensitiveness to light. The rate at which it prints is very much modified, and, as a rule, the slower the printing the less satisfactory the result.

The paper I employed, and which I will call normal paper, was prepared as follows:—Ordinary albumenised paper was floated for three minutes on a fifty-grain to the ounce solution of nitrate of silver. Four sheets were thus treated; after the last sheet had been floated the solution was returned to the bottle and the dish washed out, and then about three pints of distilled water were poured in; each sheet was floated on this for about three minutes; this water was then poured out and replaced by a fresh three pints, and the washing by floatation repeated. The paper was after each floating thrown over some blotting-paper on a line, albumenised surface upwards. This was done on Saturday morning; in the evening, when the paper was thoroughly air-dry, each sheet was folded into four quarters and placed in a 12×10 printing frame.

The printing was done on Monday and Tuesday, so that the paper was kept about seventy-eight hours between the sensitising and toning.

The first thing to ascertain was what kind of print could be obtained from this my normal paper. It printed but slowly, and the finished result is not very satisfactory.

In most cases I have printed from two negatives paper treated in identically the same manner. One of these negatives takes twice as long to print as the other.

My next experiment was to try the effect of fuming, *i.e.*, of subjecting the normal paper to the influence of ammonia gas either previous to or during the printing. Two pieces of paper were placed in a box containing ammonia in a saucer, and left there for about twenty minutes, and then printed; the results yielded in this case are far in advance of the normal paper. In order to fume the paper during the printing I took a whole sheet of blotting-paper and folded it so that it was of eight thicknesses, then, having unfolded it, placed it in the fuming box for about a quarter of an hour; at the end of that time it was again folded and at once placed in contact with the back of the normal paper which had already been adjusted on the negative. The result in this case is intermediate between the non-fumed and the fumed. In order to prevent the too rapid escape of the ammonia from the fumed blotting-paper or pad a piece of paraffined paper was placed between it and the back.

Finding that the simple washing of the paper had only partly desensitised it, I was curious to ascertain what would happen if the whole of the pure nitrate of silver were removed from the paper before printing. In order to effect this I washed the normal paper in three changes of water for about four or five minutes each, and then immersed the paper in a dilute solution of chlorate of sodium (common salt). It was again worked in a couple of changes of water, and then dried. The print obtained in this way was very poor indeed, in fact, the most unsatisfactory of all. I then fumed the other piece that

had been thus treated, and though it gave a better print the result is far from satisfactory.

Citrate of soda has frequently been recommended as a preservative when applied to the back of sensitive paper, but, as far as I am aware, no one has shown what its influence is on the quality of the resulting print, or on the time required to produce a sufficiently deep impression. I therefore treated some of my normal paper with a ten per cent. solution of neutral citrate of soda back and front; and in order to find out how such paper would print fumed and unfumed, instead of printing two separate pieces under each negative, I covered one half of the paper when placed on the negative with paraffined paper, and then I placed on the whole pads of blotting-paper, which had been fumed. The portion subjected to the action of the ammonia gave a slightly better image, but the difference was not so great as I expected. A better result would most probably have been obtained had the paper been actually fumed instead of the pads. It was in consequence of this result that I thought it would be better in future to fume the paper before printing, instead of doing it during the operation. The time required to produce a sufficiently dark print was much longer than with normal fumed paper.

At our last meeting in Birmingham a paper was read on behalf of Mr. Watmough Webster, on the preservation of sensitised paper by means of paper impregnated with dry carbonate of soda, and I thought it might be useful to ascertain the effect of this salt, when actually in the paper, before and during printing. The results I have obtained on paper treated to a ten per cent. solution of the salts are not very good; the prints are what one usually calls *mealy*, and I noticed that those pieces whose backs were floated on this salt became very absorbent, resembling very much certain brands of ready-sensitised paper which one comes across at times. Two pieces I fumed before printing, and the results obtained by this method are, I think, equal to the very best that I have obtained by any of the treatments to which I have subjected the paper. In several cases I floated the front of the paper only on the salt in solution, in others I treated the fronts of some and backs of others to the salt in order to see what the difference is, and in the case of the carbonate of soda-treated paper the result is decidedly in favour of the back being treated and fumed afterwards.

Rochelle salt (double tartrate of potassium and sodium) has frequently been recommended in different formulæ for printing-out papers, and Mr. J. Barker was, I think, among the first to work out a printing process in which gelatine was used as the vehicle and tartrate of silver one of the sensitive compounds, and I therefore thought some useful information might be obtained by treating paper with a ten per cent. solution of Rochelle salt, as undoubtedly the remaining free nitrate of silver would be converted partly into tartrate. The prints produced on the paper thus treated are poor and mealy, but when the paper has been fumed the results are very satisfactory.

The last set of experiments I made was to treat the paper with nitrite of potash, a salt which I think Captain Abney has at different times recommended in conjunction with others as a preservative. In all cases when trying the effects of salts as preservatives, the first consideration ought to be the effect it has on the image independent of its preserving action. In the case of nitrite of potash I find it to improve very considerably the quality of the resulting print when used by itself. I do not know whether this is due to the nitrite or to the fact that this is an alkaline salt, and the alkaline nature of the salt may have acted beneficially. When fumed with ammonia there is not such a marked difference as in the other cases. Nitrite of potash, therefore, seems to confer a quality on the paper not possessed by the paper when treated with any of the other salts I have employed.

At the meeting of the London and Provincial Photographic Association it was suggested that I should see what could be produced on paper prepared in the same manner as the other but unwashed, and I have therefore added to the series of prints one from each negative on plain freshly sensitised paper.

When time will allow I propose continuing these experiments so as to find out the effects of other salts on washed paper, and, if possible, to work out as regards their preserving action those which are the most promising.

A SUGGESTION FOR A METHOD OF ASCERTAINING THE COMPARATIVE RAPIDITY AND PRINTING VALUE OF GELATINO-BROMIDE PLATES.

By EDWARD DUNMORE.

A RELIABLE method of ascertaining the *practical* value of the sensitiveness of gelatine plates is, to use a stock expression, "a want long felt." Many ingenious devices have from time to time been suggested, Mr. Warnerke's sensitometer being, perhaps, the best—still this, as

manufactured, is far from being uniform and above suspicion as a guide. In the suggestion I am about to make, my idea is to have a reliable standard of comparison, so that a negative can be justly estimated as to its printing qualities, and the length of exposure required to produce it by any one skilled in photography or otherwise. Hitherto, the plan has been to ascertain how the strongest image can be made with the weakest light, under certain specified conditions, a film giving the most detail and strength when exposed for a definite time to somewhat weak artificial light being deemed most sensitive. Now, if the effect of weak artificial light was identical in its effect with strong daylight, no doubt the results would be more reliable, but this does not seem, to judge by ordinary practice, to be the case.

In the first instance, I propose to make a series of standard negatives of convenient size, say one inch square or thereabouts, as follows: Take any good, not too rapid plate, expose on an ordinary well-lighted landscape for the necessary time (this expression, although indefinite in itself, is easily understood as a period sufficient to impress an image on the sensitive film, so that it is in the best condition for development), this time might be determined by choosing a light that will produce a certain tint on a strip of sensitive paper, such as used for actinometers. A very close approximation to uniformity in the quality of the light would be thus obtained. Use a stop, say No. 128 U.S. We will assume it requires an exposure of three seconds to produce the best image. Several exposures, however, might be made to be certain of this. Secondly, make a series of exposures of the same subject in the same light for varying times, from one-tenth of a second to eight seconds, thus, one-tenth, one-fifth, one-fourth, one-half—1, 2, 3, 4, 5, 6, 7, 8. It stands to reason if No. 3, taking the numbers to represent seconds and fractions of seconds, is right, the others will be too much or too little exposed, as the development, which must be for a definite time, all the negatives being developed together, would show either under or over exposure. The developer itself should be one whose constituents are not likely to vary. By this means we obtain a series of negatives of varying qualities, which may be arranged in two rows of five each on one plate, and to each the time of exposure should be attached. These are now our gauge negatives, and can be reproduced in any quantities, identical in all respects, by means of a carbon transparency and copying. All we have to do, to ascertain the comparative rapidity of a plate, is to make a proper exposure on the plate to be tested and develop it by a similar developer and compare the results with the gauge plate; this will show the actual printing value of the negative, which is practically all we require. If the exposure is less than for the best exposure on the gauge, we at once see that it is a more rapid plate; if more, then it is a slower one. I am inclined to think that a direct comparison with a known high-quality image would be the most useful plan of estimating the printing quality of a negative the photographer could adopt, and a plan that especially recommends itself to those who only have the opportunity of practising occasionally.

As already stated last week Mr. Muybridge occupied the remainder of the evening with his illustrated lecture on "Animal Locomotion."

Thursday, the 22nd, was devoted during the day to excursions up the river, one being in a launch to Hampton Court from Richmond Bridge, provided by Mr. S. H. Fry, the other being to Kew Gardens and Observatory. Having formed one of this latter party, we are enabled to say that the leaders, Mr. F. P. Cembrano and Mr. R. L. Kidd, left nothing undone for the comfort of the party. After the lunch at the "Greyhound" Inn, an American gentleman of the party, Rev. Mr. Murell, of Florida, gave expression to the satisfaction he had derived from fraternising with them on that occasion, which led another gentleman present to say that America had so far been well represented at the Convention, there having been present residents of Florida in the south, Canada in the north, New York in the east, and California in the west, besides several others not situated at such extremes. At Kew Observatory the visitors were received by Mr. G. M. Whipple, B.Sc., F.R.A.S., who had not only granted permission, but had made a special journey from Deal to attend personally to the comfort of the visitors and conduct them over the building. We made a note of the various things there seen with the intention of apprising our readers of them at an early date.

"Mr. Whipple's kind forethought" (says the *Richmond and Twickenham Times*) "had suggested a pleasant addition to the programme, and the afternoon's inspection of scientific apparatus was followed by tea, to which he invited the members of the Convention. Mr. R. L. Kidd having expressed the thanks of the whole party to Mr. Whipple and his assistants, who so ably seconded him, was followed by Mr. Taylor in the same strain. Mr. Whipple having replied in a few re-

marks, the party retraced their way to the station after a permanent *souvenir* of the visit had been secured in the form of a group of the visitors and the Observatory staff, photographed by Mr. Scotton, of Derby." Having received from Mr. Scotton a proof of his group, we are enabled to pronounce it all that can be desired.

In the evening a report on Standards was read (see page 574), and remitted to the Committee.

Mr. Bothamley then read a paper on Orthochromatic Photography.

ORTHOCHROMATIC PHOTOGRAPHY WITH GELATIN PLATES.

By C. H. BOTHAMLEY, F.I.C., F.C.S.

To address the Convention again on orthochromatic photography presents some little difficulty, because on the one hand there are many in my audience who are well acquainted with the subject, whilst on the other hand there are some to whom it is not so familiar, and possibly even some to whom orthochromatic photography is only a name. I take it, however, that at this jubilee meeting of photographers it is desirable that the papers should, as far as possible, represent the present position of our knowledge, and I will therefore venture to recapitulate the main points that are already established.

Ordinary gelatin plates fail to represent coloured objects with their proper degrees of relative brightness, or, as artists say, with true "values," because the plates are most sensitive to blue and violet rays, much less sensitive to green, and very slightly sensitive to yellow, orange, and red; whilst the human eye is most sensitive to yellow, somewhat less sensitive to green and orange, still less sensitive to red, and least sensitive of all to blue and violet. The rays which produce the greatest effect on a photographic plate are those which produce the least effect on the eye, and *vice versa*. As a necessary consequence, blue and violet objects are, in a photograph, much too bright, whilst green, yellow, orange, and red objects are much too dark. It follows that all photographs on ordinary plates of flowers, fruit, paintings, and similar objects are unsatisfactory; in landscape work the foliage is much too dark, and has lost much of its roundness, water reflecting the light from the sky is much too bright, and a slight blue haze, almost imperceptible to the eye, is sufficient to blot out all the delicate details of the distance, on which the beauty of a view so often depends; in portraiture the flesh tints are much too heavy, and any freckles or similar defects become glaringly prominent.

To some extent these defects may be removed by interposing somewhere between the object and the plate a transparent yellow screen, which absorbs and cuts off the greater part of the blue and violet rays, and gives the green, yellow, and orange rays time to act without any accompanying reversal. True values, however, can never be obtained in this way, because ordinary plates are always more sensitive to green than to yellow, and, moreover, the total sensitiveness to green, yellow, and orange is so small, that under these conditions the exposure required is several hundred times the ordinary exposure. The negatives, too, are usually very deficient in vigour.

Vogel found, in 1873, that by treating plates with certain colouring matters, and especially with certain coal-tar dyes, they can be made sensitive to the green, yellow, orange, and red, or, as we may term them collectively, the less refrangible rays. The value of eosin for this purpose was first pointed out by Waterhouse in 1876, and Tailfer in 1882 was the first to obtain useful results with gelatin plates, and end which he achieved by the simultaneous application of eosin and an alkali.

Subsequent experiments, and especially those of Eder, have shown that the only dyes of practical value are cyanin and the dyes of the eosin group. These may either be added to the emulsion, or applied to ordinary plates in the form of a bath. In the first case the dye is either added to the materials before emulsifying, or to the melted emulsion before coating. According to Tailfer's specification it is necessary to add ammonia or some other alkali at the same time. In the second case the plates are immersed for a short time in a dilute aqueous or alcoholic solution of the dye, either with or without a certain quantity of ammonia. Sometimes the plate is immersed in a preliminary bath of very dilute ammonia, and sometimes it is washed after treatment with the dye solution, but neither of these courses is essential. A special modification of the bath method of sensitising has been described by Ives, and will be referred to again later on.

My previous communications have dealt mainly with the comparative values of the various dyes of the eosin group, which is a somewhat large group; the efficiency of these and of cyanin so far as regards obtaining true "values;" and the relative merits of sen-

sensitising in the emulsion or by means of a bath. I also exhibited the results of a number of experiments made with a view to ascertain the value of the methods from a practical photographic point of view. Stated as briefly as possible, the general conclusions arrived at were as follows:—For all classes of work orthochromatic methods have considerable, and often very great, advantages over the ordinary method. This, in fact, is generally recognised, and these methods are now widely and largely applied in the reproduction of paintings, in microphotography, and in all kinds of work in which coloured objects are dealt with. In landscape work their application is not so general, at any rate in this country, mainly, I believe, because the methods of working required to obtain satisfactory results are not yet generally known and diffused amongst photographers. Orthochromatic methods do certainly require more thought and skill than the ordinary method, and cannot be worked successfully in an unthinking and mechanical way. In the second place, I take it as established that although plates sensitised by means of a bath are somewhat, though not very much, inferior in keeping qualities to those sensitised in the emulsion, they have a much higher sensitiveness to the less refrangible rays. The testimony from many sources in favour of this conclusion is, in fact, overwhelming. Further, erythrosin, applied with ammonia, gives the highest sensitiveness at present obtainable, but the relative sensitiveness to green is too high, and the values obtained are not quite correct; erythrosin without ammonia gives less sensitiveness, but somewhat truer values; rose Bengal with ammonia gives better values than can be obtained with any other single sensitizer, though the degree of sensitiveness is lower than with ammoniacal erythrosin; cyanin is the only dye of practical value as a sensitizer for orange and red, and should be used in conjunction with erythrosin or, better, rose Bengal, for all objects in which orange and red are at all prominent or important. One of the most important results which I obtained early in my experiments was the fact that a very considerable degree of sensitiveness can be obtained with a bath of erythrosin or rose Bengal containing no alkali at all; with the first dye, in fact, applied simply in aqueous solution, the sensitiveness to the less refrangible rays is as great as that of the commercial isochromatic plates which are prepared according to Tailfer's specification by adding the dye and ammonia to the materials before emulsifying. I understand that Mr. Bedford obtained a similar result when sensitising in the emulsion. Another interesting result was that, contrary to the statements of some experimenters, I obtained the same sensitiveness with an ammoniacal solution of ordinary erythrosin as with a solution of silver erythrosin. This conclusion has been amply confirmed by the later and more extensive experiments of Professor Zettnow, published in *Phot. Correspondenz* in the early part of this year.

Lastly, with all methods of sensitising at present known, the relative sensitiveness to blue and violet remains much too great, and correct values can only be obtained by using a transparent yellow screen to absorb and cut off the greater part of the blue and violet rays.

The bath processes having proved to be the most efficient, it seemed desirable to investigate the various modifications which have been proposed, with a view to determine the best method of working. It was already known that the best degree of concentration of the bath depends on the nature of the dye to be used; that a bath too concentrated gives less sensitiveness; and that considerably greater sensitiveness can be obtained when an ammoniacal bath is used than with a simple aqueous solution. It was customary to treat the plates with a preliminary bath of plain ammonia of one or two per cent. It is stated in the Tailfer specification that it is better to add alcohol to the bath, and that the plates should be washed after treatment. The English exploiter of this patent has indeed repeatedly asserted that this last part of the process is quite indispensable. Three points then require quantitative investigation: viz., the necessity for or advantage of a preliminary bath; the influence of alcohol in the bath; the necessity for or advantage of washing after treatment with the dye.

The methods of measurement were the same as I described last year. The prepared plates were exposed for ten seconds to the light of the amyl acetate lamp at a distance of one metre, the plate being in contact with a Warnerke sensitometer screen immediately in front of which was a tank containing a one per cent. solution of picric acid two centimetres in thickness, which cut off all the rays more refrangible than the Fraunhofer line *b*. The plates were all developed together in the same dish, for three minutes, with a developer containing in each fluid ounce two grains of pyro, one grain of ammonium bromide, and four minims of liquor ammonia, '880. The details of the experiments are given in the following table. The plates used were Edwards's Instantaneous and Wratten & Wainwright's Ordinary.

The dye was erythrosin, and with Edwards's plates the bath contained one per cent. of ammonia, and with Wratten's plates two per cent. No preliminary bath was used, and the time of immersion was two minutes.

A second set of experiments, with special reference to the preliminary bath, was made with Edwards's plates and Paget Prize Plates XXX.

Dye.	Preliminary Bath.	After-treatment.	Sensitometer.	
			Edwards.	Paget.
1:10000	... None.	... Not washed.	... 25-22	15-15
1:10000	... 1 p. c. ammonia.	... Not washed.	... 23-22	15-15
1:10000	... None.	... Washed.	... 23	15
1:10000	... 1 p. c. ammonia.	... Washed.	... 22	15
1: 5000	... None.	... Not washed.	... 22-25	15
1: 5000	... 1 p. c. ammonia.	... Not washed.	... 25-24	15-15
1: 5000	... None.	... Washed.	... 25	15
1: 5000	... 1 p. c. ammonia.	... Washed.	... 22	15

Both sets of experiments were of course made in duplicate. The slight deviations are due to the difficulty of accurately measuring the exposures with the amyl acetate lamp in its original form. Where two numbers are given, the first was obtained with good commercial erythrosin, and the second with specially purified erythrosin.

The conclusions to be drawn from these results are:—(1), Alcohol up to ten per cent. has no influence whatever, and may be dispensed with in all cases where the dye is soluble in water: alcohol in larger proportion produces a distinct decrease in sensitiveness. (2), With a concentration of the dye up to 1:5000 the washing after immersion is quite unnecessary. (3), The preliminary bath may be omitted. It is further to be noticed that nothing is gained, at any rate with these three brands of plates, by increasing the concentration of the bath from 1 in 10000 to 1 in 5000. I believe, however, that with plates which have been prepared with hard gelatin or which have been treated with chrome alum, it is advisable to use the stronger bath, or to increase the time of immersion.

Ives's method consists in flooding the plate with an alcoholic solution of the dye (containing one grain in four ounces), allowing the alcohol to evaporate, and then washing with water. It was not easy to see why this method should give better results than simply immersing the plate in an aqueous solution of the dye. Photo-metric experiments confirm this supposition. They also confirm Ives's statement that if the plate is treated with the strong alcoholic solution and not washed no sensitiveness to the less refrangible rays is obtained, doubtless because the alcoholic solution does not really penetrate the film. I was unable to get satisfactory results with cyanin in this way. I observed also that some films showed a great tendency to leave the glass altogether, a result due to the contractile influence of the alcohol.

Abney's method of sensitising by means of a collodion or varnish film has completely failed in my hands.

It appears, then, that the best results are obtained in the simplest way. Dust the plate, immerse it for two or three minutes in a solution containing—

Dye solution (1:1000).....	1-2 parts.
Ammonia (ten per cent.)	1 part.*
Water	8 parts.

Allow the plate to drain for some time, place the lower edge on blotting-paper in order to take off the ridge of liquid which collects there, and dry in the dark in a pure atmosphere. Develop in ruby light with a developer containing about two grains of sodium or potassium meta-sulphite per ounce, in order to keep the liquid clear and thus enable the process to be more readily watched. As a rule,

* I believe I ought to point out that the use of an eosin dye with ammonia in this way is covered by Tailfer's patent. The ammonia may be left out if erythrosin or rose Bengal is used, but five or six times the exposure will be required.

density is obtained more easily than with ordinary plates, and it is not necessary, and often not desirable, to have more than one grain of pyro in each fluid ounce.

Turning now to the question of the use of orthochromatic methods for landscape work, I think I may say that the results exhibited at Birmingham last year were accepted as showing that these methods have considerable advantages over the ordinary method, the improvement being most noticeable in the rendering of foliage, water, and distance. (*Four sets of results obtained in spring, summer, and autumn, were exhibited in the form of lantern slides.*) I have since endeavoured to compare the various kinds of orthochromatic plates from this point of view, the comparison including:—(1), Ordinary plates. (2), Edwards's isochromatic plates, used without a screen. (3), Obernetter-Vogel silver erythrosin plates, used without a screen. (4), Plates treated with an ammoniacal bath of erythrosin, and used with a pale yellow screen.

It seems necessary to point out once more that the whole value of comparisons of this kind depends entirely upon whether the experiments have been made fairly and without bias. I do not hesitate to say that many of the so-called comparative results which are exhibited are not fair. In very many cases, for example, the results shown as having been obtained with ordinary plates are very much inferior to the results which might have been obtained if the plates had been properly managed. In all cases the quality of the values obtained depends very largely upon exposure and development, a fact which is by no means sufficiently recognised. Many of the bad, nay, wretched, results, so far as regards values, which are commonly exhibited, are due to insufficient exposure. If I have not been fair myself in the experiments which I bring before you, it is from want of ability and not from intention. I am an investigator and not an advocate. We have certainly not yet reached finality in orthochromatic processes, but a knowledge of the relative merits of the methods which we do already has considerable practical value.

In the first place, I have made a number of comparative exposures with Edwards's isochromatic plates and ordinary plates, both being used without any screen. The ordinary plates were Thomas's thickly coated landscape, Wratten & Wainwright's Ordinary. (*The subjects exhibited were Worcester Cathedral from across the river; Kirkstall Abbey; a view from Bolton Abbey, with distance and foliage; and a group with foliage.*) The differences are comparatively slight. As a rule, I do not think they are greater than might result from different exposure and development of the same plate. There is, at any rate, nothing approaching the striking differences observed when a yellow screen is used. In the case of the group, the isochromatic plate has a distinct advantage, but this was done rather late in the evening, when nature herself had provided a yellow screen in the shape of the water vapour and minute dust particles through which the rays of the setting sun have to pass. Many other experiments besides those shown lead to exactly the same result, and I believe my experience in this respect coincides with that of many other workers.

I have also made comparative experiments with ordinary plates (Paget Prize Plates XXX and Wratten's Ordinary) and the Obernetter-Vogel silver erythrosin plates. Here I have found a distinctly greater difference. (*Subjects shown: Knaresboro', foliage, water, and distance; Bolton Woods, ditto; Warwick, foliage and water.*) There is, as a rule, a distinct improvement over the ordinary plate in the rendering of foliage, water, and distance, and I consider the differences greater than could arise simply from differences in manipulation. I have exposed a very considerable number of these plates, independently of comparative experiments, and an examination of the results leads to the same conclusions. The plates, however, are not particularly easy to manipulate, and some experience is required to obtain the best results. They show a decided tendency to fog with an excess of ammonia, especially if the proportion of bromide of procedure is to put all the bromide which you intend to use into the developer at first, and then add the ammonia gradually as development proceeds. At the same time, the results obtained are not equal to those obtained with a yellow screen, although, as far as my experience goes, distinctly, but not very greatly, in advance of the Edwards's isochromatic.

Some comparative experiments were made with Obernetter-Vogel plates used without a screen, and plates prepared with ammoniacal erythrosin and used with a screen. These results (some of which are exhibited) confirm the conclusion already stated, namely, that so far as present methods are concerned, the best results are obtained with plates prepared with an ammoniacal bath of erythrosin and used with a yellow screen. If, however, the Edwards's isochromatic or Obernetter-Vogel plates are used with a yellow screen, which must be somewhat deeper in the first case than in the second, the results

obtained are not distinguishable from those obtained with bathed plates under the same conditions, but the exposures required are much longer.

This brings me to the question of the use and abuse of the yellow screen, a point which I believe to be, as a rule, very imperfectly understood. All gelatin orthochromatic plates prepared by methods at present known, remain relatively, with respect to the human eye, much too sensitive to blue and violet. The only method, therefore, of obtaining true values is to interpose between the object and the plate a transparent yellow screen, which absorbs and cuts off a certain proportion of the blue and violet rays, leaving the less refrangible rays with a relative degree of intensity and activity more nearly corresponding with their relative action on the eye. It is obvious that any variation in the tint or thickness of the screen will affect the proportion of blue and violet cut off, and hence will determine the relative activities of the various rays after they have passed through it. From an optical point of view it is desirable to keep the screen as thin as possible, but the depth of tint of the screen admits of very considerable variation. As the depth of tint of the screen increases, the amount of blue and violet cut off increases proportionally, and the relative action of the less refrangible rays on the plate, or, in other words, the relative brightness with which green, yellow, orange, and red objects are rendered increases at the same time. It is obvious, therefore, that it is easy to make a screen so intense that far too large a proportion of blue and violet is cut off; blue and violet objects will then be too dark, and green, yellow, and orange objects too light. In other words, the resulting photograph will be as incorrect in one direction as the ordinary photograph is in the other. In landscape work a screen too deep in tint causes loss of atmosphere, and with erythrosin plates under these conditions the grass and all other yellowish-green objects come out much too light. This effect is well seen in the examples exhibited. For landscapes the proper tint of screen is pale lemon-yellow; for paintings and similar subjects the depth of screen required is usually greater, and is determined by circumstances. Examples were shown illustrating the bad effects of a screen too deep in tint.

The great advantage of the screen in landscape work is that it prevents the failures, or, at any rate, want of complete success, which often results from the presence of a slight blue haze. The details in the distance, which so greatly increase the beauty of many landscapes, are rendered much more satisfactorily, and the more correct values obtained produce a roundness of the foliage, a transparency in the water, and a separation of the various planes of the picture which is rarely, if ever, attained in any other way. This kind of effect is easily seen by looking at any ordinary view with the naked eye and then through a piece of yellow glass; the increased roundness of the objects and the separation of the planes is very striking.

It has been claimed as an advantage for commercial orthochromatic plates that they can be used without a screen, which of course is true, but the results obtained are not such as to lead any one to be enthusiastic about them. It seems as if an attempt were to be made to set up as the ideal of orthochromatic photography a plate which requires no screen. Given that the plate corresponded in sensitiveness with the human eye, that ideal would be realised, but we are some distance from realisation, at present, so far as gelatin plates are concerned. Moreover, it seems to me that the use of a screen, with the possibility of varying it to suit the work in hand or the result which it is desired to obtain, places in the hands of the artistic photographer a power which he would be unwise to cast aside. With the so-called photographer, who expects his apparatus and plates to do all the thinking for him, I am not at all concerned.

Not very long ago Colonel Waterhouse communicated to the Photographic Society of Great Britain the results of photographing the spectrum on plates treated with *rhodamin*, a comparatively new colouring matter similar to eosin in constitution. I have been able to make a few experiments with a view to ascertain its value for photographic work. The magnitude of its sensitising effect was compared with that of erythrosin in the manner already described. Ordinary rhodamin prepared by the Badische Anilin und Soda Fabrik was used, and also some of the same rhodamin which had been purified. The results obtained are given in the form of a table. No preliminary bath was used, and the plates were not washed after treatment with the dye solution.

Sensitiser.	Ammonia.	Sensitometer.		
		Ilford Rapid.	Pall Mall Rapid.	Wratten's Ordinary.
Erythrosin 1:10000	1 per cent.	16	15	11
Rhodamin coml. 1:10000	1 per cent.	12	4	5
" " 1: 5000	1 per cent.	15	7	7
Rhodamin purif. 1:10000	1 per cent.	10	3	5
" " 1: 5000	1 per cent.	15	7	6

It will be seen that with one brand of plate the sensitiveness approaches that obtained with erythrosin, but with the other brands it is considerably lower.

The numbers show clearly the influence of the concentration of the dye; they show also the influence of the nature of the plate. They seem to show that the sensitiveness to the less refrangible rays obtained with rhodamin does not depend on the original sensitiveness of the plate, and that variations in the nature of the plate do not affect rhodamin in the same way as erythrosin. These and other points, however, require further investigation.

I also used plates sensitised with rhodamin to copy some paintings, and obtained results which promise well for the utility of this sensitiser. The experiments were not sufficiently numerous to justify me in bringing them before the Convention. In fact, the photometric experiments must only be taken as provisional, and are liable to correction by subsequent work. I thought, however, the Convention would be glad to have some idea as to the probable utility of this compound, and I hope to have become better acquainted with its peculiarities and capabilities before our next meeting.

On Friday there was an excursion by steamer to Gravesend, under the leadership of Mr. J. J. Briginshaw, after which the members of the Convention, to the number of between seventy and eighty, dined in the Café Royal, Regent-street, the President in the chair. To the toast of the Convention, Mr. J. J. Briginshaw, Hon. Secretary, responded; that of the photographic press being coupled with the names of Mr. J. Traill Taylor and Mr. Henry Sturmev, who responded. Mr. William Lang, of Glasgow, did like duty for kindred photographic societies. What with songs, recitations, conjuring tricks, and friendly chat, a very pleasant evening was passed.

On Saturday, the General Committee and Council for the next year were elected, and after the members had been photographed by Mr. Friese Greene in the quadrangle of Burlington House, there was a general separation.

Several papers other than those above given were presented to the Convention, but for want of time were taken as read. These will appear in our next issue.

The next meeting will be held in Chester, under the presidency of Mr. C. H. Bothamley, of Leeds.

The London daily and weekly press, with scarcely an exception, have given notices, some of them at considerable length, of the proceedings of the Convention, its nature, and scope.

There was a fair display of pictures in the galleries, and a very good display of apparatus in the body of the hall.

The showcase of Mr. J. H. Dallmeyer contained a large and choice collection of the lenses manufactured by this house, and one feature in it was unusually interesting, consisting as it did of lenses shown in the various stages of progress, from the rough-cast discs of optical glass, as received from the glass maker, up to the same after it had been subjected to the optician's skill, and was turned out ground, polished, and centred. An exhibition of this nature proves highly educational, and it seemed to be highly appreciated by those by whom it was always being examined.

Messrs. Newton & Co., whose exhibits at photographic gatherings of this nature have hitherto been "conspicuous by absence," made a magnificent show of highly-finished lanterns and scientific appliances, including a patent electric projecting microscope by Messrs. Wright & Newton. This is fitted with a new form of arc lamp of about 3000 candle-power, standing on Newton's traversing table, by means of which the light is kept in the axis. This instrument works with powers as high as one-twelfth and one-sixteenth immersion, and with lower objectives shows a blow-fly's tongue forty feet long. On one lantern was shown the microscopic attachment used by Mr. T. E. Freshwater in photographing the objects on the same table. Of these we have three before us while we write: they are in the form of lantern slides and comprise a male and female flea and a spider's foot. They are characterised by sharpness without hardness; indeed, we have seldom, if ever, seen a finer pair of fleas, which, although when projected on the screen, or for that matter when examined in the hand, cause a kind of shudder, yet do not fail to elicit a feeling of admiration at the wonderful structure of—

"Those little fleas,
Which do us tease."

A large triple lantern of very high finish was also shown, and by

its side the "Miniature" lantern—the smallest full-power lantern ever made, and which is now familiar to those in the metropolis who attend the meetings of photographic societies at which lantern demonstrations are given. This firm also exhibited a large number of slides in sets, coloured and uncoloured, these being mounted in juxtaposition. The colouring was admirably done, and by comparison with the plain ones showed photographers of how much their monochromatic productions were capable.

(To be continued.)

THE PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM. LONDON MEETING, 1889.

REPORT OF COMMITTEE UPON LENS STANDARDS.

(To the President and Council.)

GENTLEMEN,—Your Committee, appointed at the Birmingham meeting of Convention to consider and report upon the best means of securing uniformity in diaphragms and flanges of photographic lenses and lens mounts, have now the honour of submitting the result of their investigations to the Council.

Having gone very carefully into the merits and demerits of the metric and other systems advocated by various scientific opticians and others, your Committee have no hesitation in generally recommending the adoption of such portions of the "standards" of the Photographic Society of Great Britain (with such modifications and additions) as are set forth below:—

"With regard to diaphragms, we recommend—

"1st. That the aperture of the standard-unit diaphragm should have a diameter equal to one-fourth the equivalent focus of the lens, and be marked '1,' the approximate equivalent focal length of the lens itself being engraved on the mount.

"2nd. That diaphragms with smaller openings should have apertures diminishing in area to the extent of one-half from the unit standard downwards, and be marked successively, 2—4—8—16—32—64, &c. These numbers would indicate to the practical photographer that if a given sensitive film requires with the unit stop an exposure of one second, the introduction of a smaller one would necessitate an exposure of as many seconds as the numbers marked on it; in other words, each step would require double the exposure of the preceding one.

"Should a lens not admit of a diaphragm with an aperture as large in diameter as one-fourth its focal length, nor exactly any one of the above-mentioned sizes, we still recommend that all the apertures be made in uniformity with the above scale, with the exception of the largest, which should be marked with the number its area requires in relation to the unit diaphragm. In the case of a lens having a working aperture exceeding in diameter one-fourth its focal length, the diaphragms should be marked in fractions (as $\frac{1}{5}$, $\frac{1}{25}$, &c.) in uniformity with the standard apertures, according to the sizes of their relative apertures.

"[We further advise that diaphragms required to be made with apertures intermediate to the standard sizes should invariably be marked with numbers corresponding to the ratio of their area to the aperture of the unit diaphragm.]"

Note.—The paragraph marked above cannot be endorsed by your Committee.

FLANGES.

"We advise the construction of flanges with internal and external screw threads of a standard series, for attachment to cameras having screw threads adapted for screws, $1\frac{1}{2}$ in., 2 in., $2\frac{1}{2}$ in., 3 in., in external diameter, and made with twenty-four threads to the inch.

" $3\frac{1}{2}$ -INCH.—The $3\frac{1}{2}$ -inch to have twenty-four threads to the inch on the inside, and twelve threads to the inch on the outside.

"If larger ones are required, we recommend that they increase in size one inch in diameter, from four inches upwards, with twelve threads to the inch, both internal and external. We also recommend the manufacture of a series of adapters, with inner screws made to carry any existing lenses, and with outer ones corresponding to the next or other larger size of the standard flanges above described. Hereafter, whenever practicable, the screws cut on the mounts of all newly manufactured lenses should be suited to one of the above-sized standard flanges."

These "standards" are at once intelligible and scientific, and from the fact of their already widespread use, both by the profession and amateurs, it may fairly be argued that they are generally popular and practical.

In addition to the recommendations of the Committee of the Photographic Society, as quoted above, your Committee would further suggest:

1. That besides the approximate equivalent focus being engraved upon the lens mount, the exact point from which that focus is measured be distinctly marked by a line or cross.

2. That the diaphragms be engraved with their proportionate areas to such equivalent focus thus: $f-4=1$, or $f-32=64$, and so forth.

3. That where iris diaphragms are used a *detent* be fitted to ensure accuracy in the apertures.

Your Committee would congratulate the Photographic Society of Great Britain upon the inception of a "Uniform System;" its adoption by

many of the leading photographic opticians both at home and on the Continent, and the insistence by most thoughtful workers to have their lenses constructed according to this system, being sufficient guarantees of its usefulness, and a strong proof of the necessity there has been for reform in this direction.

S. G. BECHANAN WOLLASTON.

Chairman of Committee on Lens Standards.

ON THE ACTION OF LIGHT ON ALLOTROPIC SILVER.

SINCE my last communication to this JOURNAL I have obtained the following results:—

1. It was mentioned in that paper that the red gold-coloured modification of silver was converted into a bright yellow-coloured form by the action of light. Continued exposure seems to produce little further change so long as the substance is dry. But if the paper on which the silver is extended is kept moist by a wet pad, with three or four days of good sunshine, the change goes on until the silver becomes perfectly white and is apparently changed to normal silver; water, alone, tends to darken this form of allotropic silver, accordingly the portion of the paper that was protected for comparison, darkened, showing that the whitening effect was due wholly to light.

It thus appears that light can convert yellow or red-yellow allotropic silver to white.

2. Some pieces of the very bright blue-green modification were exposed to light, and with about one day's bright sunshine they passed to a pure metallic gold colour.

It appears, therefore, that light can cause the blue-green modification to pass to the gold-yellow.

This change only occurs with a very brilliant form of the bluish-green substance, which is obtained with a quick, short washing. Specimens slowly and very thoroughly washed, which when brushed over paper gave a more mat colour, did not yield this result, but became brownish, as described in the July number of this JOURNAL. Nor can this result be obtained with the soluble form of allotropic silver described in the June number of this JOURNAL.

Light, therefore, can change the bluish-green to the yellow modification, and this last (with the aid of moisture) to white normal silver. The silver thus obtained is pure white, lustrous, and metallic, resembling silver leaf. Organic compounds of silver reduced by light give grey or black silver devoid of lustre.

American Journal of Science for August.

THROUGH JAPAN WITH A CAMERA.

CHAPTER X.—NIKKO—JAPANESE TEMPLES—RELIGION IN JAPAN.

OUR work at Sendai was soon over, and we might have gone further on our travels, but we did not like the idea of travelling the ninety miles or so of the somewhat uninteresting road between Sendai and Koriyama (the nearest railway station) for the third time. There is a railway line between the two towns just mentioned, but it is not yet opened. The engineer in charge, however, kindly offered to let us travel on a ballast train, and we decided so to do, although it would keep us for several days longer in Sendai. I believe the truth was, we were in no great hurry to leave; we had so completely lost our hearts to the Bamboo and the Chrysanthemum, the charms of young ladies who, in addition to other attractions, could stand on their heads, having proved too much for us. However that may be, the ballast train somehow or other went without us; but we are all the slaves of time, so one evening saw us packing up our luggage, and at four o'clock next morning, long before it was light, the girls came romping and shouting into our room, pulling down the "mosquito houses" on the top of us to indicate that we must be marching. At the first streaks of dawn we were on the road, "Sayonara,"+ the sweet-sounding parting greeting of the Japanese, long called after us.

So we did this somewhat weary road from Sendai to Koriyama for the third time.

By this time the excessive heat was over, and the people were beginning to resume their clothes. During the very hot weather their raiment had been of the scantiest. The men wore merely the narrowest of loin bands; the women, for the most part, wore a single Japanese garment, (like a dressing-gown), but threw it off their bodies from the waist upwards. The children under eight or nine went scampering about stark naked.

Nagasaki and myself both took train at Koriyama, but the former went straight on to Tokio. Our business was over, but I had some ten or twelve days more of holiday, and had no desire to get back to the steaming atmosphere of the capital sooner than I had to. Besides, I wished to see the great town of Nikko. I therefore left the train at

* The pad used was of unbleached muslin, which was boiled several times with distilled water to remove everything soluble before use.

+ Pronounced like sigh-oh-nara. Literal meaning, "if it must be so."

Utsunomiya, from which town Nikko is about twenty-five miles distant. The road is one continuous avenue of stupendous pine trees.

Nikko is the Rome of Japan. It is a city of temples, or, more strictly speaking, it is a very small town surrounded with innumerable temples, which are, for the most part, amongst the trees which cover the sides of the mountains around the town.

The natural situation of Nikko is very beautiful. It is surrounded with mountains of very considerable height, all wooded to the very top with pine trees. There are deep valleys and gorges between these, with swift mountain torrents and cataracts flowing through them. The town itself is a single street, running parallel with one of these streams.

To give any idea of a Japanese temple is a most difficult thing, especially as there are temples of at least two distinctly different religions, namely, Buddhism and Shinto. One thing that is noticeable, and contrasts favourably with certain things at home, is that the priests of the different religions seem to carry on their offices side by side in the most perfect concord.

I have tried to discover whether the Japanese have any feeling of reverence whilst in these temples, or towards them, or anything that they represent, but it is very difficult to find a trace of any. I have seen crowds in a temple—smoking, laughing, and drinking tea. I have seen young fellows go up to the door of a temple and pull the cord attached to the bell, which, I believe, is supposed to call the attention of the Deity, laughing all the time as if it were a great joke. On the other hand, I have seen—occasionally—old men and women apparently deep in prayer.

The whole matter is very difficult to judge of, and in attempting to do so it is necessary to bear various things in mind, as, for example, that some of the temples are (I believe) not even professedly places of worship at all; and, again, that the Japanese appear to express by laughter many emotions different from those that we so express.

An anecdote may serve to illustrate the difference between the customs in Japanese temples and Christian churches. A friend of mine wished to photograph the interior of a temple. It was dark and the exposure required was long. He asked the priest how long it would be before there would be any service, and got a reply, which he understood to mean half an hour. As this would just allow him the time he required, he put up his camera; but after ten minutes had elapsed, the priest re-appeared followed by a crowd of people. "Had the honourable gentleman not finished his photograph?" "No; but, of course, if service was about to begin he would take down his camera." "Oh, by no means; the service would wait till the honourable gentleman had finished his exposure."

I forget now whether "the honourable gentleman" took advantage of the kind offer or not.

The temples vary in structure from a simple wooden canopy on four wooden posts to huge piles of the most elaborate wood-carving, filled in the inside with more carving, with gilding, painting, bronze work, lacquer work, and a general wealth of ornamentation perfectly bewildering.

These prints (which are of excellent quality—of cabinet size) were sold by a local photographer at a trifle under 2d. each. At the same shop an album containing thirty carte size silver prints could be bought for less than 1s.—and this where all the collodion-albumenised paper, &c., are to be imported from Europe.

W. K. BUNTON.

JACK AND I IN NORWAY.

No. XI.—VOSS AND EIDJE.

WE took a picture of the schoolhouse, Fleischer's temporary hotel at Voss, with Jack and me in our carriages at the door, and Fleischer himself seeing us away; we got one of the drivers to draw the shutter. I sent our landlord some pictures from this negative and he was highly pleased. He wrote me that they reached him on his birthday, and that he looked upon them as congratulation cards. This village of Voss holds a position of considerable importance, being the terminus of the railway line from Bergen, a run of sixty-five miles, passing through fifty-five tunnels on the way. The construction of this railway is considered a first-class piece of engineering. This line, when contemplated and made, was doubtless more as a means for the conveying of produce into saleable markets with more speed than they could hitherto, as the districts all round here are highly cultivated. Tourists, however, avail themselves of this line to a considerable extent in the summer-time, and certainly a more charming spot to spend a few days at so easy a travelling distance from Bergen could not be found.

There is an old stone church here (stone is unusual). It dates as far back as the thirteenth century, and is still in good preservation. We got a good picture of it in full sunlight, and the snow lying thick on the hills beyond.

The next resting-place on our way was Edje, on the Hardanger Fjord. The distance from Voss to Edje is twenty-four miles, with one resting-station between. On this journey we came upon one of those zigzag descents, as bad as that at Stalheim. It was so precipitous that we had to come out of the carriage and walk down a descent that never ceases till it reaches the valley below. On this descent there are two gigantic waterfalls, which we photographed in a mist of spray from the falls that filled the air. The bridge across the bottom of the falls was the only point we could get them from, and it is perpetually robed in this sheet of mist.

The mountains on the further side of this glen are very precipitous, with only little bits of green table-land to be seen here and there all up the front of them. In this glen we came upon one of the wire conductors used for conveying the grass when cut from the heights to the valley below. This wire is rather thicker than a telegraphic one, and it is stretched from the ground below right up to the top of the mountain. At any point on the way up the farmer has the wire line within reach. When he has cut, gathered, and bound his grass into bundles, these packets are hooked on to this wire and slide down to the end, where, by the action of a swivel movement fixed there, they drop off on to the ground, so that the collected gathering of the mountain is found in a mass at the bottom when he comes to take it away. Jack was talking to one of those hard-working fellows who seem to be wrestling continually with the hills for a living. Jack said, pointing to one of those insignificant bits of table-land that they cultivate with such care, "I can't see how it's worth your while to take all that trouble for the grass that you can take in a year off such a bit of rock."

"Bless you, sir, I will get as much pasture off that flat in a year as will be equal to the keep of one child." Then, thought I, it does not take much to keep a child in this country, or there is more grass to be taken off that rock in a year than I would give it the credit of being able to grow.

The day we travelled to Eide the road was thick with dust of a yellowish colour, fine as flour. There was a lot of carriages going our way, so that the air was filled with this dust, and the horses, conveyances, and passengers got so covered with it as to be almost past recognition. There was also considerable rivalry as to who would be first in the race, so as to get free from the swirling clouds of dust raised by the vehicle wheels in front.

The effect was very strange: hot weather, sweltering; dusty roads, blinding; and all around the tops of the hills snow-clad.

Eide, on the Hardanger Fjord, is one of the prettiest places on the tourist route. In going out to look for the best points from which to obtain views, we found that the only place we could get a good general view of Eide itself was from the water in a boat, as the hills on either side ran up from the water's edge almost perpendicularly, leaving no position from which we could photograph.

This is a beautifully green pastoral valley, a regular staying-place for the tourist, the surroundings commending themselves to the seeker after pleasant scenes, and Møland's Hotel for the seeker after pleasant times.

The garden in which the Møland house is situated is very inviting during the heat of the day, with its chairs, rustic lounges, and pleasant resting-places underneath the leafy, shady shelter from the sun. It makes us lazy; we roll, and smoke, and dream that there is no unpleasantness in this world of ours.

When here, Jack and I went away up amongst the mountains viewing a waterfall of some note, when we came on a lade of the roughest construction running on to a small paddle-wheel that kept in motion a grindstone. This was evidently erected here as a convenient place for the surrounding cottagers, wrights, and farmers to use in sharpening their tools and implements. Here a man could come and sharpen his tools without any assistance but the water, which was always there and always willing. Jack set to and sharpened his knife here just for the novelty of being able to say that it had been sharpened on a grindstone away in the midst of the mountains in Norway.

Many visitors were staying here—walking tourists, fishing tourists, newly-married tourists, and poor old tourists, who come here year after year, drawing in the fresh mountain breath to give a little more staying power to a waning life.

We met a young fellow here who had been doing a walking tour for several weeks in Norway, and from a description of his experiences it must have been very enjoyable. I thought with a light quarter-plate such an outing would be first-rate. And there is a Club in Norway (something like the Cycling Club that Jack talks about at home) that would help any one considerably who went on such a tour. The Norwegian Tourists' Club it is called, and the yearly subscription is only four shillings and eightpence. They not only give what information you require as to routes, but they make the roads easier for you by making pathways over mountains, and construct roads to waterfalls; where fording rivers are dangerous they build bridges; and in unfrequented parts of the country they erect huts for the use and comfort of the walking tourists. The members of this Society can have a badge for one shilling, which, when shown to the keepers of bridges, huts, and the like, would prove an open sesame to all the Club's possessions.

A considerable time could be profitably employed at Eide with the camera, making it a centre to work from, the surrounding scenery within easy distance being so well suited for photography. We intended to go on to Odde from here, but found that our time would not allow us.

We started from Eide for Bergen, a nine hours' sail. We had a very congenial company on board, all of the passengers being the visitors from Møland's Hotel, who were all more or less acquainted with each other, so that the intercourse was of a freer nature, and the interchange of ideas amidst the most interesting scenery made the passage very enjoyable indeed. We got some negatives of ships sailing and groups at the quays as we sailed along.

As we continue sailing in and out of the vandykes of the sea on this the last day of our ploughing Norwegian waters, we have leisure to draw

the threads of thought together and note the impressions of unfamiliar things that live with us.

It seemed to me that the land here belongs peculiarly to the people. With the exception of Mr. Gade, the American Consul's place—Fantoft—which is a country-seat near Bergen, we never in all our travels came upon what might be a gentleman's residence and grounds (they have no nobility). The country was all farms, farms, farms—and small at that. When on one of the fjords one day our boatman pointed up to the shelving rocks overhead covered green with grass, with a little house fixed against the rocks three-quarters up the mountain—"That's my brother's farm," he said; "isn't it a good one?"—well, we would not have taken it in a present. Still, it was about as good as most of the others we saw.

With regard to the general stock on these farms, and even on the valley ones, which show up better, it is meagre and scarce; you come across some goats, a cow or two, sheep very rarely. The only things in seeming plenty are horses, and they are very willing and good workers. I have seen one of these brutes, when out feeding on the roadside, jump the gates and follow our vehicle for miles; in fact, we could not get rid of him until he was caught and tied up in some station-house till we got away. Then they would free him, and he would trot quietly home again.

Birds are also very scarce here; I never heard any but one kind—and I cannot give it a name—chirping away in the woods all the time; we heard them, but seldom saw them. A gull or two might be seen flitting across our way in the fjords, but never in quantity as we have them at home in like situations. The very severe winter may have something to do with the paucity of the feathered tribe, although they are well cared for by their friend, the farmer, in the winter-time, who nails up boxes against his steading as homes for them in the winter, and hoists little bundles of corn on the top of long poles so that they might get food when their natural supply is lying deep under the snow.

We did not see many flowers, neither wild nor cultivated; on the tops of the mountains in some places we found heather in plenty, but the flower on it seemed the bloom of the previous year, for it all fell to pieces when pulled. The colour of the bloom was nearly white.

One thing that attracted and amused us very much while travelling here was the long distances the children of the little villages or hamlets would run to open the gates for the conveyance to pass through, in anticipation of the little *tip* they invariably expected and got. I have seen them scamper over a mile, by short cuts through the fields, to get up to the gate before the vehicle came up. And then there would be some doubt who should get the small coin, as rival parties usually started at the same time, and in breathless expectation each waited to see who was to be richer by the run.

MARK OUTE.

PORTRAITS BY PHOTOGRAPHY.

FIFTY years is not a long period of time in a historical retrospect, and yet it is sufficiently long to change the face of many things, long enough to remould the manners and customs of a race, long enough to mellow civilisation to deeper tints and a richer flavour. The story of the inventions and discoveries which have ministered to the convenience and comfort of civilised man during the last half century seem like fairy tales, yet a few years of familiarity and we forget that they were not coeval with the creation.

Fifty years ago, this leafy month of June, the tidings reached our shores that a Frenchman had discovered a method whereby the image given by a lens could be materialised. Since then a generation, substantially, have laid down in their graves, leaving behind them, *en masse*, the mirrored image of their faces—the only generation, so far as we know, since the morning stars first sang together. The faces of the dead and absent no longer flicker in the expiring recollection of the living, and *silhouettes* have ceased to grace the walls of the guest chamber. Year by year the little miniature—the first born of Daguerre's process—has given place to others of larger size and more pictorial value, until to-day camera portraits are too common to excite remark. It is of these larger products of the camera that I wish to say a word. Size has been attained, and now let us have something better than size. It must be admitted that an overwhelming majority of these pictures are crude to the rankest degree, and miss altogether the flavour that is of the most vital importance in portraiture. The vehement enthusiasm which is expended in maintaining that pictures by photography are works of art would be more wisely directed if applied to the study of artistic principles and effects. But, aside from this, we encounter far greater difficulties in portrait sizes than in making smaller work, for various reasons, prominent among which is the limitation of lenses. It seems to me that we have no lenses as yet suited to life sizes. Work of this sort usually bears upon its face the evidence that the instrument has been strained far beyond its powers. The definition may be all that could be desired, but the portrait is like a map—the pictorial effect, the atmosphere, wholly unattained. The great sensitiveness of gelatine plates permits the use of lenses of much longer focus than any we have for images approaching

life size. We all know how much better we can make small sizes—cabinets for instance—with a lens designed for larger work; the distortion of the head or figure is then no longer seen. Many sitters object to pictures showing their hands, for the reason that "they will look so large." They have been accustomed to seeing work with too small or too short-focussed lenses, and their objections are well founded. But small pictures are often seen now from the hands of skilful men, who are properly equipped with lenses, with the values perfectly kept. This may be attained in large as well as small pictures when we have lenses to meet the requirements of such work. The euryscope and others of kindred construction may very properly be used for groups and architectural work, but for portrait busts grant us an instrument of fourfold illumination and length of focus. Such lenses may reasonably be looked for in the future, I think; it is only just now that the great Lick telescope has taken up the work that astronomers have all along been trying to do with their spy-glasses. And when the coming photographer surveys the life-size image upon his plate—a size within the easy powers of the instrument used in its production—may the time have also come when the cramped and niggling work, now known as retouching, shall no longer be allowed to run riot over its fair proportions, but, instead, the work of the artist, supplementing its value by broad and skilful treatment. Then let the prints be made upon cartoon, or some other paper with a rough surface, which will not expand to the distortion of the image or repel artistic taste by its vulgar gloss.

Some maintain that enlargements by the solar process cover all this ground, but it seems to me that there is a value in direct work, when intelligently done, that is not successfully rivalled by other methods. This worthy style of portraiture appeals to the great middle class, who cannot well afford the work of competent portrait painters; and it is hazarding very little to predict that it will be largely known among the products of the second half century of photography.

By GUSTINE L. HURD.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

AUGUST 27.—Mr. John Spiller in the chair.

Mr. W. England handed round some negatives, one of them instantaneous, taken on celluloid films, developed with eikonogen. They were of neutral blackish colour, and were admired for their good qualities of cleanliness, clearness, and vigour.

Mr. A. COWAN remarked that negatives developed with eikonogen were of different colour according to whether sulphite was used, and when so used, according to the kind of sulphite employed. It was important also not to add nitric acid to the eikonogen solution with the view of enhancing its keeping properties. Such an addition was quite unnecessary, and even in small quantity had the effect of so filling the solution with precipitate that a spoon would stand up in it. Meta-bisulphite did not cause a precipitate but made the developer very slow.

Mr. ENGLAND then showed the lenses and shutter employed for taking the pictures (stereoscopic) that had been handed round. They were purchased in Paris during a visit to the Exhibition, and were very good as well as moderate in price. The lenses were of the rapid Steinheil type. The pictures shown had been produced with full aperture. The shutter was on the whole the most satisfactory that he had used. Mr. England also showed an appliance, previously described in our report of the London and Provincial Photographic Association, for fixing lenses to the camera front.

Mr. FRIESE GREENE said that cardboard fronts in place of ebonite had been shown at the late Congress.

Mr. CHAPMAN JONES showed a globe lens made by Harrison in 1862. It had been stated that these lenses covered a very wide angle, but this was not the case, as would be evident from the distance separating the lenses. There was, however, a remarkably flat field.

Mr. W. E. DEBENHAM inquired whether there was not a strong flare spot.

Mr. JONES replied that there was, and the CHAIRMAN said that one was formerly in use at Woolwich Arsenal, but the flare spot was very troublesome.

Mr. Jones next showed some lenses made by Swift for detective cameras working with an aperture of $f/4$.

Mr. DEBENHAM asked whether the field was fairly flat.

Mr. JONES replied, wonderfully flat. He also inquired Mr. Bolas's opinion as to whether it was desirable for a detective camera to have so large an aperture as $f/4$.

Mr. T. BOLAS replied that it was sometimes desirable to have the quickest lens obtainable.

Mr. McLAUGHLIN, from Ontario, Canada, being invited by the Chairman to address the meeting, said that in Canada they gained almost all their photographic information from the English journals. In the government photographic work, in which he was engaged, there was a great deal of printing by the blue process. He had been informed that in one department alone there was a saving effected by the employment of photography instead of draughtsmen of twenty thousand dollars a-year.

The CHAIRMAN inquired whether Mr. McLaughlin used any special means for clearing the lines in negatives for reproduction processes.

Mr. McLAUGHLIN replied that he developed his plates (wet collodion) with iron rather acid, and intensified with copper.

Mr. Greene showed a transparency on a 20×16 plate printed by contact from a negative taken last Saturday of the members of the Photographic Convention.

BATH PHOTOGRAPHIC SOCIETY.

ON Saturday last, the 24th instant, an excursion was made to Wick Rocks. The party of ladies and gentlemen left the city about noon by brake. The route lay along the Upper Bristol-road, through the villages of Kelston and Bitton. At the latter place a halt was made to photograph the rural church and its surroundings.

Arrived at Wick Rocks, and luncheon partaken of, subjects for the camera were quickly found and taken. At half-past five p.m. a start homewards was made, journeying by way of Cold Ashton and the Gloucester-road. The scenery along the route is of a picturesque and varied character, and the drive of some fifteen miles or more was greatly enjoyed.

Glastonbury has been selected for the next outing, on September 21, and the first ordinary meeting after the recess will be held at the Royal Literary and Scientific Institution on Wednesday evening, September 25.

Correspondence.

Correspondents should never write on both sides of the paper.

INTERNATIONAL CONGRESS ON PHOTOGRAPHY.

THE International Photographic Congress met at half-past two o'clock on Wednesday, the 7th instant, M. Marey, *membre de l'Institut*, in the chair. The work to be undertaken was again not taken in the order we find it in the preliminary report, but with the sixth question: "Uniformity in the size of photographic plates." Great discussion followed, and every effort was made by the Congress to endeavour to adopt a size in conformity with the foreign sizes in daily use. It was found regrettable that such a great number of different size cameras should be in the market, as a great benefit would accrue could an universal size be adopted for the future. The Congress adopted the size 18×24 as a standard, it being the most convenient. Cut into halves or quarters, or doubled, in every way the form or shape is adapted for landscapes, &c.

The fifth question was discussed on Thursday, the 8th instant, M. Davanne in the chair. M. de Villecholle was the reporter of the second Commission. Fifth question: "Find an uniform and easy method to adapt divers lenses on the different size cameras." The Commission proposed that a given number of flanges or rings, of a given size, screwing one into the other, should be adopted. M. Molteni proposed his "*adaptateur*," which I described in a former letter to THE BRITISH JOURNAL OF PHOTOGRAPHY. (This system I myself find very good, providing a safety screw be placed upon the apparatus, otherwise the risk is run that the lens may fall out and get broken.)

M. de Villecholle also proposed a modification of the above. He takes a piece of sheet-iron or zinc, of the exact size of the front board, and pierces a circular hole in its centre, through which the screw of the lens is passed; the ring or flange of the lens is then screwed on and nips the zinc front, and thus keeps the whole tight. The zinc front is then introduced into the camera. Naturally a zinc plate is necessary for every size lens. This system has the advantage of doing away with the necessity of screwing the flange of the lens upon a wood front-board.

The Congress then considered the advisability of a standard size and shape for said fronts of cameras.

The discussion then commenced upon "An uniform-sized screw for fixing cameras upon any kind of stand." After a long discussion it was decided that, as the Whitworth screw-thread had already been adopted by the Photographic Society of Great Britain, the Congress should accept it as well. This was decided on.

The Congress met again on Friday, the 9th instant. The discussion took place upon the ninth question: "Custom House formalities for the circulation of sensitive preparations."

As a dark room is about to be provided in almost every Custom House, the Congress thought wise to adopt a kind of international sign or label—a sign upon a red ground, and in the centre three letters, C. I. P. (*Congrès International de Photographie*). An inscription to be added in the language of the sender as well as the receiver—"To be opened only in the

presence of the owner." If by transit, the language of the country or countries through which the parcel passes can be added.

The discussion then began on the tenth question, M. Perrot de Chaumcux being the reporter. This gentleman, being a very experienced lawyer, gave the Congress the history of the French laws on artistic property for the last hundred years, and pointed out so clearly the advantages and disadvantages of accepting or not adopting the conclusions of his report that an unanimous vote was obtained.

The Congress met again on Saturday, the 10th instant, to discuss the second question, which had been proposed by the first Commission—"Uniformity in the Method of Measuring the Focal Length of Lenses"—Mons. A. Martin, reporter. Great diversity of opinion was here exhibited. The standard diaphragms of the Photographic Society of Great Britain were commented on, and a great desire to adopt them was manifested. Finally, the proposed method of the Commission was voted.

The Congress then chose Tuesday for their next meeting.

The General Secretary of the Congress then informed the members that on Thursday next, being a holiday, M. Marey, Directeur de la Station Physiologique du Collège de France, had invited the members of the Congress to visit his establishment.

M. l'Amiral Mouchez had likewise invited the Congress to visit l'Observatoire de Paris on Friday evening at nine o'clock.

M. Janssen desired the Congress to visit his Observatoire at Meudon on Sunday, the 18th instant, at three o'clock.

A few words on a personal matter. I cannot endorse the opinion expressed on the Congress by an editorial contributor in the last number of *The British Journal of Photography*, nor the words of the eminent Mr. Leon Warnerke, spoken before the Photographic Society of Great Britain on July 23 last.

The Photographic Society of France has been very liberal, kind, and generous to all foreign members of the Congress. They have not "had to pay a heavy subscription in the first place, and to look after themselves as best they can." Mr. J. Smith, accompanied by Mr. Braham, assisted at one of the *séances*. M. Pector, as they told me, refused to accept the ten francs, as he believed them to be delegates.

M. Leon Warnerke has also been received with the greatest honours. Last night he was invited to the banquet, and the post of honour given him. What these gentlemen would have received had they been delegates I know not. Your correspondent also received a free invitation, but was called to account by the President on arriving, on account of that article which was supposed to have been written by me. I was placed in such a position at table as not to be able to glean anything of the speeches made, which would, I am certain, have interested my readers.

On Tuesday, the 13th instant, the members of the Congress met again at 76, Rue des Petits Champs, Paris, under the presidency of M. Marey, *membre de l'Institut*.

An animated discussion began on the third question, "Uniformity in the indication of the photometric effect of diaphragms." The Congress decided on adopting, as the normal size corresponding to the unity of exposure, the diaphragm admitting light by an opening equal to the tenth of the focal distance of the lens. The Congress expressed the desire that all the other diaphragms should be so chosen as to be able to change the duration of the exposure, taking this unity as a basis, and that all diaphragms should have corresponding numbers engraved upon them, showing their *rapport* with the normal one.

On Wednesday, M. Davanne conducted the debates. The third and fourth questions were taken into consideration. The fourth question, "Uniformity in the method of measuring the duration of the admission of light regulated by obturators (shutters),"

The Congress, after a long discussion, decided that the duration of the total action of the opening and closing of the flanges of the instrument should be engraved on the obturator in seconds and fractions of a second, as well as the effective working expressed by the report to said duration. This to be calculated by comparison with an ideal instantaneous obturator. These items are to be given for the largest diaphragm which can be used with such obturator as well as for the principal degrees of tension which can be attained, or at least for the extreme rapidity.

The first question, "The introduction in photography of a fixed unit of light." The Congress adopted the luminosity produced by a surface of one square centimetre of incandescent platinum at the moment of solidification, which unit has already been adopted by *savants* under the name of "Unit of Light Vielle."

As a more practical unit or standard, the Congress adopted the flame of the Amyle Acetate Lamp, the intensity of which is to be calculated after that of the Unit Vielle. The flame of the Amyle Acetate Lamp to be employed in its most luminous part, the remainder to be cut off by means of a square sheet of metal, having a horizontal cut along its surface.

Subsidiary question A, "Uniformity in the estimation of luminous intensity in photographic operations." The Congress admitted that the luminous intensity of objects to be photographed could be determined by the employment of photometric apparatus, as proposed by M. Masent. A commission was appointed to study and experiment on the same.

Subsidiary question B, "Unity in the method of determining the sensitiveness of photographic preparations." The Congress adopted the method proposed by M. Janssen, that of obtaining a given tint by direct exposure to a standard light for a given time and developed under certain conditions. M. Janssen, in order to make this system more easy, ini-

tiated the Congress into the method to obtain a series of standard tints to facilitate said measures. For gelatino-bromide plates the standard light to be the flame of the Amyle Acetate Lamp (as modified by the Congress), placed at the distance of one metre from the sensitive surface; the exposures to be made at intervals of five seconds.

The Congress draws attention to the sensitometer Warnerke as able to render service, but in conjunction with the Amyle Acetate Lamp, and not with the phosphorescent plate.

Thursday being a national *fête* for France, the Congress did not meet, but accepted the invitation of M. Marey to pay a visit to his scientific establishment at Auteuil. At three o'clock we were all at the rendezvous. M. Marey exhibited and explained the different instruments he had invented to decompose motion by the aid of photography. The flight of birds, the motion of animals, as well as the different attitudes of the "superior beings," man, were all analysed and brought to a geometrical figure. His photographic gun was examined with interest, but what created most astonishment in most of the visitors was when they heard that the exposure of one ten-thousandth part of a second was not rapid enough to have the wing of a fly sharply delineated.

On Friday, the 16th, the Congress again met, M. Marey in the chair. The Congress proposed that another Congress should meet in 1890 at Brussels, in order to continue the work began. A permanent Commission was named, not only to prepare the work for the future Congress, but to enforce as far as possible the decisions of the present one. The Congress adopted a special mark to distinguish the apparatus made in conformity with the wishes of the Congress. The mark or stamp to be a rising sun with a monogram in the centre. All the standards which have been voted by the Congress are to be deposited in the photographic section "du Conservatoire des Arts et Métiers à Paris."

The same evening, at half-past nine, the Congress paid a visit to the "Observatoire de Paris." We were received by Messrs. Wolf and Henry, astronomers attached to the establishment, who kindly showed us all the instruments, and explained their scientific use. In order to go from one building to another the paths of the garden were studded with lamps, which vied with the constellations above, shining brighter than the starry firmament. A beautiful sight was obtained from the roof of the "Observatoire." Paris, illuminated with its thousands of gas jets; the Eiffel Tower, piercing the clouds in flames, as it were, by the Bengal fires burning between its mighty iron girders; the captive balloon lighted up by the reflected lights of the illuminated fountains of the Exhibition, resembled an extraordinary moon, or a fiery meteor about to bring destruction on the "modern Babylon;" the deep shadows cast by domes bearing the telescopes threw a gloom around; all appeared strange and unaccountable—a fairy land, a residence of spectres, or a scene of Dante. After two hours' visit to this sanctuary of learning we returned home, commenting upon the self-sacrifice of astronomers for their love of science, &c.

On Saturday the Congress met "au Trocadero," under the presidency of M. Janssen, for their *séance de clôture*. A recapitulation was gone through of the work accomplished. The foreign members were thanked, and cordially invited to the next Congress, to be held at Brussels. The President declared in the name of the *Ministre* that the "Congrès International de Photographie" of 1889 had terminated its work and was dissolved.

On Sunday, by special invitation, the members of the late Congress visited the Physical and Astronomical Observatory of M. Janssen, situated at Meudon, a short distance from Paris. The eminent astronomer awaited us at the entry gate of the establishment, and introduced us into the stables of the château (destroyed by the Prussians during the siege of Paris). These stables, about eighty yards long, were transformed into an immense laboratory. Apparatus of every description, size, and form—air pumps, gas reservoirs, meters, gas bags—encumbered the place. M. Janssen drew our attention to a series of three-inch iron pipes joined together so as to form a length of about sixty metres, each end being stopped by a thick glass. M. Janssen informed us that these long tubes were intended to contain different gases, under a pressure of 200 atmospheres; a ray of light was then sent through, and a spectroscopical examination then followed. Another apparatus for the spectroscopical examination of steam at different pressures was described. All these appliances have for their object the solving of the natural mysteries of the planetary bodies revolving through space. M. Stanciewitch, Professeur de Physique à l'Académie Royale de Guerre à Belgrade, assisted M. Janssen in his explanations.

The photographic department was then visited, and the apparatus in which such large negatives of the sun are obtained every morning (weather permitting) was carefully examined. The rapid obturator invented by M. Janssen, by which an exposure of one-hundred-thousandth part of a second can be obtained, the complicated mechanism and its working, was clearly and ably explained by the astronomer.

M. Pasteur, the clever operator, showed us a series of negatives of the orb of light. Its spot, their numerous changes, its atmosphere, and its revolutions were explained. A large print of the sun's surface, containing spots, was kindly offered by M. Janssen as a *souvenir* of the visit to his establishment. We then went across the park to see the new telescope, after which photographic negatives were taken by M. Fabre of groups of the late Congress. A lunch was then offered by the Directeur (M. Janssen), who was heartily thanked for the interesting and, above all, instructive demonstration, as well as for his hospitality.

On Monday evening, the 19th inst., the Photographic Society of France

invited all the foreign members and the delegates to a splendid banquet, organized in memory of the fifty years elapsed since the introduction of photography.

The celebrated Edison was one of the guests. Many speeches of great importance for the history of photography were made, of which I am sorry your correspondent cannot give a *resumé*, having been placed by error too far from the orators.

On Tuesday M. Janssen gave a lecture on the work and doings of the late Congress—in fact a *resumé* of all I have related in my letters to *THE BRITISH JOURNAL OF PHOTOGRAPHY*.

The Congress, in a short time, has done good work for the future of photography. It has laid a basis for future work, and has publicly shown that photography is an art well worthy of the solicitude of the State and the attention of *sarants*. A few years ago the latter would have thought it below their dignity to intermix with the adepts of the black art, or lose their valuable time in giving their attention to a problem in the interest of the Daguerrian art. PROF. E. STEBBING.

196, Rue Legendre.

NATURALISTIC PHOTOGRAPHY.

To the Editor.

SIR,—If I had not said all I have to say at present on naturalistic photography several times over, I should have been glad to discuss the subject with Mr. Graham Balfour—whose letter on your favourable notice of my book appears in your last—feeling sure that I should meet with fairness and good temper, for in this respect Mr. Balfour differs widely from his leader.

To my mind the subject has been thoroughly threshed out in words; it is now time for works. The Exhibition of the Photographic Society of Great Britain is now within measurable distance. Let Mr. Graham Balfour, Dr. Emerson, and other naturalists, show us examples of what they mean; let them justify the faith that is in them. It would be only fair, not only to myself, but to photographers generally, that after so much excited theory the naturalists should show us a little of the results when reduced to practice. I believe I shall be on the hanging committee, and I will take care that as far as my influence will go they shall have fair play, which, however, they would have had anyway.

I may be answered that in that case they would have to compete with the whole body of Philistine photographers, and the contest would not be equal. But there is "another way," as Mrs. Glass would say, in which they could bring all their out-of-focus batteries to bear on one man, one which the one man would gladly welcome. In October there will be an exhibition of my works at the Camera Club; I have no time to consult the authorities before writing this letter, but I have little doubt they would admit a collection of naturalistic productions for comparison. If it should be said that there will be no room, I would gladly give up some of mine.

I thus offer two opportunities of converting photographers to their peculiar doctrines, which the naturalists should not allow to slip.—I am, yours, &c.,

H. P. ROBINSON.

AMERICAN CONVENTION.

To the Editor.

SIR,—I herewith send you the following letter from my son Gavin, who is an amateur, residing in Boston, U.S.A. If you think his report of the Photographic Convention held there the early part of this month is worthy of publication, it is at your service.—I am, yours, &c.,

JAS. ALEX. FORREST.

Waverley, Alexandra-road, Birkenhead, August 26, 1889.

BOSTON, MASS., August 14, 1889.

"I am about to tell you what I saw at the Photographers' Convention held in Boston last week. The Eastman Company showed a new camera with celluloid film roller. This material is said to be a great improvement over the paper, both as to transparency and manipulation; the roller includes a hundred negatives and has an indicator attachment which tallies each plate as well as numbers those exposed. The prints I saw were very good, though I am not prepared to say they equal the best glass productions. Anthony's 'Climax' negative films are of a thicker kind, and if the sample negative I saw, as well as the prints were a fair exhibit, they are next to perfect; there was a picture of a young girl and no retouching, yet the print was as soft and finished as it is possible in best portrait work. I saw a swivel lens attachment, to avoid the nuisance of tilting the camera in taking high buildings or anything below a level focus; the lens could be moved the same as if on a ball socket, and in no way distorted the object of vision. There were exhibits of head rests made on the ball-socket principle, and so delicate in movement they could be made to act like the evolutions of a man's wrist.

"It may be rather late to introduce a new kind of head-rest in these days of instantaneous photography, yet even now the best artists use them in their best class of work. There were five exhibits, in three sets each, of illustrations taken from Longfellow's poem of *Evangeline*; they were all very fine, but the one selected for the prize surpassed anything I ever saw; it took right hold of

you like some masterpiece in oil, and had that mark of genius subtle as a gossamer. Saturday I went on excursion with the photographers some miles down the coast; we dined on board, and altogether were sailing some five hours. It was a most enjoyable trip. Coming home the cameras were in full force—'Kodaks,' 'Lilliputs,' detectives, &c.; and I have no doubt there were some nice yacht views captured. One artist, who took the silver medal for marine views, had a camera, the most ingenious get-up I have yet seen. The box was fixed on a gun-stock, the trigger so placed to work the lens shutter, while the operator sighted his object along the barrel, at the end of which there was fixed a finder; the moment he saw the picture in his finder away went the trigger, when the picture was taken!

"I overheard a conversation on formulae between Mr. Michael and Mr. Cramer. The former is considered the finest artist in the country, while Mr. Cramer is the largest plate maker, perhaps, in the world. Mr. Michael's formula was the quintessence of simplicity, and like the story of the young man who asked Sir Joshua Reynolds how he mixed his colours, 'With brains, Sir!' Mr. Cramer said there was really no fear of over developing, as the negative could always be reduced with red prussiate of potash and hypo, and in the case of local reduction the same remedy applied with a brush would always correct an over exposure. Mr. Michael said that was all very well, but no amount of doctoring would substitute bad workmanship, and to secure the best work you must have the best conditions.

"A few remarks occurred about the temperature and seasons, and how in summer you required far less alkali in your developer than in winter.

"Leeds ivory films' for positives—the samples of which I saw were splendid work, and I think more than likely to displace opal.

"Glass is fast losing its hold as a photographic film holder.

"GAVIN ALEX. FORREST."

DEVELOPOIDS.

To the Editor.

SIR,—On returning to town, my attention has been drawn to your notice of the compressed developer I have introduced under the name of "Developoids," and, if you will allow me, I should like to make a slight correction.

I believe I am right in stating the two-grain pellets made by Dr. George S. Sinclair contained pyrogallie acid alone; those I supply contain in addition a restrainer, viz., bromide of ammonium. All that is required, therefore, is to dissolve one of the pellets in one and a half ounces of water and then add from two to six drops of liquid ammonia, .880, when the developer is ready for use. For a quarter-plate one pellet is required, for a half, two pellets, and so on in proportion. These "developoids" work admirably with the Ilford and Britannia plates, and, indeed, with any other make requiring pyro and ammonia development.—I am, yours, &c.,

T. H. POWELL.

116, Denmark-hill, S.E., August 26, 1889.

[Dr. Sinclair's "pellets" certainly were composed of pure pyrogallie acid only, no restrainer being present.—Ed.]

EXHIBITION OF THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

To the Editor.

SIR,—With reference to the recent decision of this Society to form a museum of photography, the Council invites members and others to send for exhibition any photographic curiosities of historical interest in connexion with photography.

Such articles as are approved by the Council will be shown during the time that the Exhibition is open, without charge to the owners, and will be returned, carriage paid, at the close of the Exhibition.

Exhibitors will oblige by writing a short description of the articles sent, and by also stating whether they would be willing to give, bequeath, or sell them to the Society.

The exhibits should be sent c/o Mr. J. Bourlett, 17, Nassau-street, Middlesex Hospital, London, so as to arrive not later than Wednesday, September 18.—I am, yours, &c.,

A. M. MANTELL, R.E., Hon. Sec.

ANGULAR MEASUREMENT OF THE SUN.

To the Editor.

SIR,—I note a letter in your last issue by Mr. E. Dunmore, in which he states the sun in a 15 x 12 landscape would be represented one-sixteenth of an inch in size, but he does not state what focus lens would give that size. Now, taking a twenty-two-inch focus lens, you would have the sun about a quarter of an inch in diameter, and to get it the size he mentions, one-sixteenth of an inch, a lens less than ten-inch focus should be used.—I am, yours, &c.,

W. R. KENNAN.

7, Kenilworth-square, Ruthmines, Dublin, August 26, 1889.

ERRATUM.—Instead of the initials "C. R." attached to the article, *Round the Fleet with an Instantograph*, in last number, read "C. A."

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting of this Club, September 4, 1889, will be *The Best Shutter for Detective Cameras*. Saturday outing at Strand-on-the-Green, Kew Bridge Station.

Exchange Column.

- Will exchange one interior and one exterior background for two others.—Address, J. GRIMSHAW, Photographer, Haslingden.
- I will exchange a geared hot and cold rolling press, fifteen-inch plated rollers, for modern photographic outfit, whole-plate or stereoscopic preferred.—Address, W. WALKER, 156, Noel-street, Nottingham.
- Will exchange Optimus 7x5 enryscope, new condition, for half-plate Ross' rapid symmetrical or larger enryscope. Difference, if any, adjusted.—Address, E. A. BASEBE, 6, Hartest-terrace, Mill-road, Cambridge.

Answers to Correspondents.

All matters for the text portion of this JOURNAL, including queries for "Answers" and "Exchanges," must be addressed to "THE EDITOR," 2, York-street, Covent Garden, London, W.C. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.

PHOTOGRAPHS REGISTERED:—

- A. Macdonald, Brodick.—Two photographs of a boulder. One photograph of cliff and boulder. One photograph from the summit of "Goatfell."

DEVIZES.—Such a stopper would certainly prove useful.

R. W. (Manchester).—Design unsuitable for registration as a trade mark.

J. J. A.—For permission to photograph in Kew Gardens, write to the director. It will be readily accorded.

L. J. W.—Evidently the plates have been made a long time. That will account for the iridescent appearance at the margins.

J. JONES.—Do not trouble about purifying the potassium iodide, but obtain, instead, a fresh sample from a respectable chemist.

GEO. F. BARTY.—To obtain permission for photographing ruins in Rome, apply at the Office for Preservation of Ancient Monuments there.

WAX.—Only oils and varnishes are employed for diluting the pigments employed in colouring lantern transparencies. Wax is not used.

F. DUNSTERVILLE.—The formula is as given by the author. Take the proportions of the salts as given and try with different quantities of water.

W. VERY.—The mere fact of a patent being sealed does not make it valid. If the apparatus was in public use before the application was made the patent is of no value whatever.

O. P. T.—The cheap views, such as you describe sold at watering places, are merely lithographs varnished. They are got up and printed in a colour to resemble photographs; indeed, they are sold as such at some of the bazaars.

J. WILLIAMS.—No one can prevent you from photographing the church, provided you do it from the public highway or where you are not trespassing on private property. No local photographer can have the sole right of photographing the village church.

R. STANLEY.—Your difficulty is only imaginary; collodion of all the recognised brands may still be obtained of the different makers or through any of the dealers in photographic materials. You see there is no necessity, in face of this, for the insertion of your somewhat caustic letter.

A. KIDD (Perth).—To take two different views of a face in one negative and by one exposure, all that is necessary is to place a mirror behind and to one side of the head. If this be at a very slight inclination, and the face of the sitter be directed towards the camera, a second and different view of the face will be seen in the mirror.

CLOUDY writes: "Will you be kind enough to inform me how to make a good cloud negative? I have tried, but cannot get any contrast. I tried a quick exposure with small stop, but did not succeed."—If there were good contrasts in the clouds and they were not obtained in the negative, over exposure was, no doubt, the cause. Try again with less exposure.

NEMO.—As you get the effect you desire on a dull day, all you have to do is to imitate the conditions on a bright one by the judicious use of blinds. It is impossible for us, not having seen the studio, to suggest the manner of procedure. Study the conditions well when the effect is as you require, and note them, then you ought to have no difficulty in repeating it in every-day work.

CHLORIDE.—If you wish to eliminate the hyposulphite of soda quickly and effectually from your prints, do it by washing. By decomposing the "hypo" you will get products which, if not removed, may prove as hurtful to the pictures as the hyposulphite of soda, and which are quite as, if not more, difficult to eliminate than the hypo. "Eliminators" should never be used until it is surmised that the fixing agent and its products are washed out—as a safeguard, in fact.

S. HARDY says that he has recently taken a house and shop on a lease, with permission to build a studio on the top of the house. Since he has commenced building it the superior landlord has served him with notice to pull it down, as being contrary to the covenants of the original lease. He asks whether he can be compelled to do so, seeing that his landlord has given him permission for the building.—This is a matter for a solicitor. But it is clear that if a man grants to another a right which he himself does not possess it is of no value. Our correspondent will, no doubt, be able to recover damages for the expense he has been put to from the one who granted him the lease, if the facts be as stated.

ZINC O. inquires: "Can you tell me where I can obtain, in small quantity, pure zinc plate for photo-etching, and its probable cost. I have tried several places without success. As I want it for experimental purposes only, I do not require a large quantity at a time."—Pure zinc plate is not an article of commerce. Pure zinc may be obtained of operative chemists, but not in the form of plates. Zinc plates suitable for photo-etching are supplied by all dealers in lithographic materials.

NOT IN FOCUS.—For large heads the single combination of the maker named will do all you can desire, but for groups we would give preference to the 10x8 rapid rectilinear.

X. Y. Z. writes: "Will you please inform me, through your 'Answers to Correspondents' column, what would be the best course to adopt? Some few weeks ago I sent three negatives for enlargement on porcelain; the enlargements arrived, but two out of the three were broken, owing to the careless packing, but they have not sent the negatives. I went to the Post Office about it, and they said I should have to claim from the sender. I have written repeatedly, and can neither get my negatives or a reply, and the people will not have the order, as it has been so long on hand. It is three weeks since I wrote first and have not heard yet."—If the pictures were imperfectly packed the Post Office is not liable for the injury, but the senders. Sue the enlargers in the County Court for the damage and also for the value of the negatives. You will have to prove in the case of the opals that it was through carelessness that the damage arose, as they will, no doubt, plead that, according to "custom of trade," they are not liable for injury in transit. This, of course, does not apply to the negatives which they still retain. If you issue a summons the firm will, doubtless, be glad to compromise the matter rather than allow it to go into Court, and thus gain publicity.

W. D. says: "Yesterday I wished to make a new nitrate of silver bath for some wet plate work (slides); I find it all wrong, however, and I want to know if you can tell me how to put it right? I dissolved one ounce of silver in two ounces of water, then I dissolved half a grain (possibly one grain) of iodide of potash in one ounce of water, and added this to the silver solution. The yellow precipitate disappeared all right, but on adding water to make up the bath to fourteen ounces a dense white precipitate formed, which afterwards turned black in the light. I filtered it twice, but could not get it clear. My old bath is perfectly bright and sparkling. I have had it in the sun to-day, but it does not clear. I have never had trouble with a silver bath before (at least at the very commencement of the life of the bath), and I have now made them on and off for seventeen or eighteen years. I cannot remember where I bought the silver; probably in a shop in our little country town. It was in a one-ounce bottle, just like you get elsewhere. The water I used was boiled rain water which had recently fallen, but collected after the house-top had been well washed. What had I better do? throw down the silver (if so, with what?) and make another bath, or is it possible to doctor this?"—In reply: In all probability the water was at fault. All appears to have gone well until the bulk was added; then a slight turbidity, not a dense deposit, should have been produced. The best plan now will be to add a little bicarbonate of soda until a permanent precipitate is produced, and then place the solution in the sun for a day or two; then filter and slightly acidify with nitric acid, when, no doubt, the bath will work all right. If this treatment fails the silver had better be precipitated as a chloride with common salt and added to the residues.

A. H. B. writes: "1. Is there any absolute way of deciding great under exposure and great over exposure of a gelatino-bromide negative? I have some lent me that are miserably thin, but not having seen their development, cannot form an idea. One or two were 'drop-shutter' exposures, but have almost the same appearance as some of my earliest attempts with a portrait lens, which I am certain were over exposed.—2. I am often annoyed by an iridescent stain on edges of negatives, not noticeable until fixed; can you form an idea of the cause, and its removal if possible?—3. What is the difference of the bromide of ammonium and the bromide of potassium in a developer, if any?—4. In enlarging from a half-plate negative with the lens that took it, is it necessary to stop it down to the same extent as when taking the negative? It is a 6x5 rapid symmetrical, and the illuminant when enlarging is best mineral oil. What I mean is, if the negative has detail microscopically defined by the use of a small stop, can this definition be reproduced with the full aperture or largest stop when enlarging, as when stopped down great loss of vigour ensues in the print, and enormously long exposure is necessary as well?—5. I am desirous of joining a good photographic club or society where I can mix with those who could help in such matters as the above. I live in Regent's-park, so one not too distant would be preferable. Any advice would be sincerely welcome."—In reply: 1. A thin negative full of detail usually implies over exposure.—2. We suggest deterioration of the plate in its incipient stage as the cause.—3. Either are used almost indiscriminately. The majority of workers prefer potassium.—4. Much depends upon the quality of the lens, but the matter can be decided by a trial conducted by the aid of a powerful magnifying glass.—5. The London and Provincial Photographic Association or the London Photographic Club.

* * We shall next week issue a group of the members of the Convention, taken by Mr. Friese Greene in front of the Royal Academy of Arts.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1531. VOL. XXXVI.—SEPTEMBER 6, 1889.

THE SIZES OF PHOTOGRAPHIC PLATES.

ONE of the questions set down for discussion at the recent Congress in Paris was the establishment of a series of standard sizes in photographic plates, a matter that presents considerably more difficulty than, perhaps, appears at first sight. We do not refer solely to the trouble arising from the difference in the national standards of measurement, nor to the existence of well-established and long-recognised sizes based upon the exigencies of those standards, but more especially to the questions of suitability to different purposes, and of taste in the matter of shape and proportion.

So far as the adoption of a universal or international series of sizes is concerned, it is from the outset unreasonable to expect that the Congress should depart from the use of the metrical system of measurement employed, not in only France, but almost universally in vogue in other Continental States; but it is equally hopeless to expect that English and American photographers will give up their *inches*, relinquish the well-known sizes of plates so long familiar to them, and commence to reckon their sensitive films in centimetres. From that point of view it is useless to attempt the establishment of any universal system until the metrical system is transplanted to British and American shores.

With regard, however, to the establishment of a more regular system in the shape or proportions of the plates in use, there is certainly room for reform, though it is far from easy to settle definitely upon any hard-and-fast standard of dimensions, or upon any particular *format* that will answer equally well for all purposes. Between the "quarter-plate," or even smaller size of the hand camera, and the 24×18 , and similar mammoth sizes still occasionally used for direct work, there is plenty of latitude for the exercise of taste as regards mere size, and perhaps the selection is better made from the heterogeneous list of existing sizes than from any carefully arranged series.

The argument has been put forward that such a system would greatly simplify matters for the makers both of cameras and of plates, but this is, we think, of comparatively little importance. Certain sizes are, and always will be, popular, and these sizes form the staple of the work, both of the apparatus manufacturer and the plate maker, while the "odd" sizes form but a small proportion of the whole. In this country, the quarter, half, and whole-plate sizes very far outnumber all others in use, while 5×4 , $7\frac{1}{2} \times 4\frac{1}{2}$, $7\frac{1}{2} \times 5$, and larger sizes are comparatively rare.

The question is an altogether different one from that of standard lens mounts, or camera screws, especially the former. English and French lenses are employed indiscriminately, regardless of the country of their origin, and it is in the highest

degree inconvenient when a large number of lenses are employed to have to provide a separate front and a separate flange for each. In the case of plates, if a camera be made to accommodate a recognised size of plate, such plates can always be readily obtained, at least in the country in which the camera was made, while even travellers in foreign countries have little trouble in filling their wants, since English plates are stocked by most of the Continental houses, and several of the English makers regularly manufacture the standard foreign sizes. It is, besides, much easier to cut down a larger size, or to have the plates specially made to the required dimensions, than to alter the national standards of measurement.

Some advantage might accrue, however, from the adoption of a systematic and systematically arranged series of sizes adapted to the standards of each country; but even here the question of taste comes into operation even more than that of convenience. Certain proportions in the dimensions of the picture are supposed to be more suitable for one class of subject than another, but it is doubtful whether any definite conclusion has ever been arrived at as to what is precisely the best shape of plate for landscapes and for portraiture respectively, or whether there is any necessity for any difference. Taking our English sizes, we have surely variety enough in shape, ranging as the dimensions do from such proportions as $7\frac{1}{2} \times 4\frac{1}{2}$ to 12×10 , and these have been indiscriminately employed from the earliest days for both portraits and landscapes.

Of late years the shapes known as "panel," "promenade," and such-like have been introduced as novelties, while occasionally we meet with pictures of a circular, square, or panoramic form. These last must, of course, be used only on subjects to which they are suited, while the more universally recognised proportions are of more general application.

This brings us to the question whether it is possible to fix upon a shape of plate which shall be, if not *the best* for all purposes, at least so proportioned that it is capable of general use. The precept has frequently been laid down, that the subject should, when at all possible, be arranged to suit the plate; but that when this is not feasible *the print* must be cut to suit the subject. On this principle, or rather on the supposition that no given shape of plate was suitable for all subjects, it was proposed some years ago to use square plates as being the form from which any shape of print could be most easily cut, but on the score of economy, no less than convenience, this practice is surely to be condemned.

Recognising the impossibility of fixing upon a shape that will prove applicable under all circumstances, we are reduced to the consideration of the question of the best for general purposes, leaving extraordinary subjects to be dealt with in

the best way possible. The almost universal opinion is that the form should be a rather narrow oblong, in preference to such proportions as 12×10 or 10×8 , which approach too closely to the square. No precise dimensions have ever been fixed, but if we may take practice as a guide, we would point to the sizes worked by such experienced landscapists as Valentine, of Dundee, and Wilson, of Aberdeen.

These firms have popularised two different sizes of pictures, namely $7\frac{1}{2} \times 5$ and 12×8 , the latter, it will be observed, being 12×10 "improved." In both these instances it will be noticed the proportions are as three to two, and certainly, from our own experience in landscape work, no less than from an inspection of the works of the two artists named, the proportions appear to be eminently suited for any kind of subject. For general portraiture, too, the form can scarcely be improved upon, whether for full-length, three-quarter, half, or merely bust. For groups also little difficulty need ever be experienced, with the aid of accessories, in satisfactorily filling the plates.

The recommendation of the French Congress is to adopt the proportions 24×18 as the normal, or $4 : 3$, also a good shape, a little broader than the one previously mentioned. But they go on to direct that other sizes be made by halving or doubling the normal. Here we think the size under the recommendation referred to is unsuitable, since it establishes two distinct and very different forms. We presume that the intention is to alter only one dimension at a time, so as to form a series 24×18 , 18×12 , 12×9 , &c., otherwise the difference between the successive sizes will be too great to be convenient. But if the series run as we have supposed, it will be seen that the proportions of each alternate size become $4 : 3$ and $3 : 2$ respectively, which, though it presents variety, is scarcely so desirable as uniformity.

But if the relative proportion be $17 : 12$, the dimensions may be altered singly and the *format* of the plates remain almost absolutely unchanged, the variation from strict accuracy being only one-third of one per cent. of the longer dimension. The next question to consider is how this will work practically without necessitating the resort to inconvenient fractions. Well, if we take a plate measuring 17 inches by 12, by halving each of the dimensions alternately, we arrive at a plate measuring $4\frac{1}{4} \times 3$, or a quarter of an inch narrower than our quarter-plate. This, though smaller, is to our mind a more pleasing shape, whether for landscape or portrait, even for that small size; and the form is, as we have said, absolutely adhered to throughout the series which runs $4\frac{1}{4} \times 3$, $6 \times 4\frac{1}{4}$, $8\frac{1}{2} \times 6$, $12 \times 8\frac{1}{2}$, 17×12 , 24×17 , &c.

Or if the narrowed quarter-plate be considered too small, we may take as our basis to work upon the half-plate increased in length by a quarter of an inch, or $6\frac{3}{4} \times 4\frac{3}{4}$. Commencing with the half of this we have the following series, which is almost as true to form as the previous one—viz., $4\frac{3}{4} \times 3\frac{3}{4}$, $6\frac{3}{4} \times 4\frac{3}{4}$, $9\frac{1}{2} \times 6\frac{3}{4}$, $13\frac{1}{2} \times 9\frac{1}{2}$, $19 \times 13\frac{1}{2}$, 27×19 , &c. Whichever series be adopted, it will be noticed that most of the existing popular sizes are closely approached, especially in the first series. If the $7\frac{1}{2} \times 5$ plate be taken as the basis, then a series of two shapes or proportions identical with the French proposal will result—viz., $5 \times 3\frac{3}{4}$, $7\frac{1}{2} \times 5$, $10 \times 7\frac{1}{2}$, 15×10 , 20×15 , and 30×20 , the proportions being alternately $4 : 3$ and $3 : 2$. This, as already stated, offers a variety, but, unfortunately, not of much use to the user of a camera of fixed size.

The establishment of a system such as this will very considerably simplify matters for the plate maker who may coat plates only of the largest size in general use, and by dividing produce

any size required. It is, perhaps, a long time before such a system will secure general adoption, but it no doubt has its advantages.

ECONOMY IN THE PRINTING ROOM.

MATERIALS AND THEIR USE.

NATURALLY, in considering economy of materials, the nitrate of silver bath occupies the foremost position, on account of the large amount of money invested in it in the course, say, of a year's work. The question of weak or strong baths will claim first place for notice in this regard. Now we will at once say that no question of economy can arise when quality of work may be interfered with: therefore, if strong baths give better results, they should be used without hesitation; if weak baths give equal results, we may discuss economy. When strong baths can also be used with the same sample of paper with equal advantage as regards quality of results, there is economy of material and economy of time and labour. Is the latter saving which is obtained when using a strong bath more than counterbalanced by any possible saving of material furthered by using a weak bath? This is all that need be considered. A sheet of paper will only decompose a certain amount of nitrate of silver, whether the paper be floated on a twenty or a hundred-grain bath; but as it will also take up about equal quantities of surplus fluid, *i.e.*, silver solution, in either case, the daily amount that will be thrown out of service in the form of print washings poured into the chloride tank must be directly proportional to the strength of the silver bath (we may disregard any consideration of the weakening of the adherent surface solution by the decomposition into chloride). Hence, if there were no waste or loss whatever of the theoretical yield of silver from the print washings, weak or strong baths would be on an equal footing as regards economy. But seeing that, as a matter of fact, there will almost always be waste, it is self-evident that the larger the quantity of silver in the print washings the greater the absolute annual waste. This may be a small fraction of the actual nitrate used, it may be a large one. *Ceteris paribus*, economy, then, is obtained by working so as to produce a minimum amount of residues.

On this principle, then, it is easy to predicate the best way of decolourising the floating bath. Kaolin has been long used for this purpose, but, seeing that it loses its properties after awhile, and a fresh supply has to be added from time to time, thus increasing the residues again, while the use of carbonate of soda is attended by little or no waste, for the carbonate of silver formed is, to a great extent, redissolved as the bath gets acid again, it follows that the carbonate plan is so much better both in this and in other respects that kaolin ought to be a thing of the past.

Regarding the albumenised paper itself, we may mention that we were recently consulted about the difficulty of cutting certain sizes out of a sheet, and when one was shown to us to illustrate the difficulty, it seemed almost insurmountable. Further consideration, however, induced us to take the actual measurements, and we found that this particular sample was more than half an inch shorter than another in our own possession, from which it is evident that paper of assumably ordinary dimensions is by no means of the same size as received from different makers. This is a very important consideration, and one that is, ordinarily, quite unknown to the majority of photographers. We have since seen sheets cut

largely to waste, because of the impossibility of gaining a particular size without loss? We are, of course, alluding to the ordinary size of paper, not the extra large, which needs a very considerable extra outlay in the shape of dishes, &c., and where economy is not necessarily obtained unless for special sizes.

Economy, too, is not necessarily consulted by cutting an unusually large number, for example, of *cartes de visite* from a single sheet, for, it must be remembered, that where there is a moderate amount of margin there is little probability of prints being wasted through slight damage to the edges during the handling necessary in the various processes a print is subjected to. On the other hand, when there is no spare margin, not only is there occasional waste from the paper being unevenly placed upon the negative, but a certain proportion of prints are rejected through frayed or torn edges. We do not, however, recommend a margin of too ample dimensions, as there would then be not only waste of paper, but waste of gold also, in that it would be unnecessarily expended upon useless margins. Economy is very largely influenced with prints with dark edges—especially the more important sizes—by cutting fairly closely to the required ultimate size.

We might, perhaps, be expected at this stage to enter into the question of the economy of the photographer making for himself the various salts, more especially those of the precious metals that he employs; but we propose devoting an article specially to this subject, and will, therefore, pass it by and conclude the present article with a reference to what is really the most important subject we have yet dealt with—the economy of the fixing bath. Our words of advice here may be very brief: "Use a maximum quantity of hypo for fixing the prints; it is the truest and best economy to use hypo with no niggard hand." This salt can now be purchased at such a low rate that there is no excuse for any photographer using a bath a second time over, or using too small a proportion to the number of prints he has to fix. Let it ever be remembered that the danger to the future stability of the prints through insufficiency in the amount or the strength of the hypo bath is entirely invisible when the prints are taken out of the bath. All the advice of experts here must be taken on credit; but no print is likely to "stand" that has been fixed in weak hypo or in too small a quantity of solution, and that a free hand with hypo is the truest and best form of economy.

NOTE.—In our last article on the subject, the printer has made us advise that a parcel over ten pounds in value should be "decreased" instead of "declared."

No sooner does an individual render him (or her) self popular or notorious, than a portrait is to be seen in most of the stationers' shop windows. It appears to matter not from whence the notoriety may proceed. It may range from philanthropy down to criminality, still "portraits" of some kind or another are forthcoming all the same. Frequently, when several portraits of the same individual are published, they are totally unlike each other. Notably is this the case with reference to the portraits of Mrs. Maybrick. Some of these from different sources now being exhibited in the windows bear no resemblance whatever to one another. What is more, the discrepancy between them cannot be charged to retouching, which is usually made the scapegoat in such instances. So much are some of the portraits at variance with each other, that one can arrive at no other conclusion than that there must be more than one "Mrs. Maybrick"—that is, if the portraits be authentic.

When, a few years ago, the Photographic Society of Great Britain after mature consideration, adopted what is known as the universal

system of diaphragms and flanges, it was imagined that this matter was definitely, and for ever, settled. The system met with approval both at home and abroad, and was generally adopted everywhere. Since then, however, different attempts have been made to alter it. The last two proposals are those emanating from the recent Photographic Congress in Paris and the Photographic Convention. If every country, society, or manufacturer were to adopt a system of their own, or any recognised system that is being continually altered, a "uniform system" may render confusion worse confounded than it was when makers simply numbered the stops of their lenses, arbitrarily, 1, 2, 3, &c., with any real reference to their ratios. Imagine, if the system of numbering the diaphragms and the uniformity of the screws were altered every few years, what would be the effect on some of the older lenses? Many of these have now been altered in conformity with the present recognised system. If this be changed, a fresh alteration or marking would be necessary, and again at the next change, so that, ultimately, the projecting metal of the diaphragm would not be large enough to contain the different figures. Neither would the brasswork of the mount be sufficiently thick to allow of the different screwthreads being, from time to time, cut upon it. Better by far to leave well alone, or, at least, till a substantial reason for an alteration is forthcoming.

PHOTOGRAPHERS who have a large stock of negatives will do well to take warning from the following case:—A very large number of negatives, the accumulation of many years in a somewhat extensive business, were stowed away in a spacious upstairs apartment. A short time back it was noticed that the floor of the room appeared to be subsiding. A builder was called in, and an examination showed that the whole of the flooring, together with the joists, from the great weight upon them, were giving way bodily. The negatives had to be at once removed to avoid accident. Then the floor had to be taken up and entirely new joists put in.

It is a very common thing for an upper room of a house to be selected and fitted up for the storage of negatives, and as they gradually accumulate more fittings are, from time to time, added. This is often done without due consideration as to whether the joists and flooring are sufficiently strong to carry the immense weight they are in the end called upon to bear. In some large establishments, of many years' standing, the weight of the accumulated negatives must be estimated by tons, and these are frequently located in the upper part of a not too substantial a building. Many photographers do well to bear the fact in mind, as, in the case of a sudden collapse, the consequences might be very serious.

PARLIAMENT is once more in vacation. Nothing was done during the past session with reference to the long-promised new Act on artistic and photographic copyright. Nor, so far as we are aware, was any allusion made to it in the House. That a new law as regards photographs is highly desirable cannot be gainsaid. In Parliament there are a goodly number of members who take a lively interest in photography, and they have already, in a very practical way, used their influence to the general advantage—as witness the provision of dark rooms at the different Custom Houses. Possibly, if these gentlemen were approached with reference to a new Copyright Bill, they might be induced to take the subject in hand next session. Why does not the Photographic Society of Great Britain, which is largely composed of professional photographers, move in the matter? This would be quite legitimate business for it to undertake.

WHAT is a permanent process in photography? Usually any process in which the image is composed of colouring matter in the form of a pigment is recognised as such. Carbon prints are generally considered as being permanent, but some of them will not bear a few weeks' exposure to a strong light without exhibiting a marked change in tint. Collotype, and other mechanical processes in which the image is in printing ink, might well be considered as permanent. We have, however, seen some collotype prints which, but a few weeks ago, were of

a rich photographic tint, but now, by the action of light, they have become changed to a totally different colour. In fact, the change, in the time, has been greater than would have been the case with ordinary silver prints. It must not be supposed that because a picture is in printers' ink that it is necessarily permanent, because many of the pigments employed in its composition may be extremely fugitive. Notably is this the case with some of the bright reds used for printing posters, as is manifest on most hoardings. Some of these fugitive reds are often employed in the inks for mechanical processes, in order to obtain the brown or purple photographic tints. Consequently, if the prints are exposed to a strong light the red becomes quickly discharged. Furthermore, it leaves the print of a far less pleasing colour than it would have been had the red not been used in the first instance. The red is not simply discharged, but usually becomes converted into a pale, dirty brown. On former occasions we have directed attention to this subject; but the tendency to use fugitive pigments in "permanent" processes appears to be increasing rather than otherwise. However, it may be mentioned that it is only exposure to light that effects the colour. It does not change spontaneously, unless exposed to its influence, as in the case of a silver print.

ON THINGS IN GENERAL.

THE Photographic Convention having become an assured success, thanks in no small degree to the unflagging, unselfish energy and industry of its Secretary (elected by acclamation, of a very hearty nature, to the same post for the forthcoming year), we may hope every meeting for increasing usefulness from its deliberations. When the first American Convention was instituted, I remember seeing extracted from its proceedings in the columns of this JOURNAL a series of useful apophthegmatical utterances, under, if I recollect aright, the name of *Convention Cameos*; but as I was reading the other day some of the papers read at the last meeting of that body I saw a great contrast, and I must express surprise that some of the matter then published was ever allowed either to be read or published. When a man can write, as did one contributor to the Convention, respecting the floating of albumenised paper on the silver bath—that there is "no danger of over-silvering. In experimenting, the writer silvered six sheets respectively—four, six, eight, ten, twelve, and fourteen minutes, in a fifty-grain bath. No difference could be noticed in the finished bath," &c.—one wonders what the Convention is for, and to whom the papers were submitted before being read, the truth being that it would be base flattery to call the man who could write such absurdities merely ignorant. I am happy to think, too, that the tone of the British Convention is too high to permit the utterance of such sentiments as we found in another paper read in America at the same time. The writer coolly advises the "average photographer," whatever that may mean, not to try experiments for himself, but to let others do that kind of thing, and then to suck their brains. Lest I should be accused of exaggeration, I give the *ipsissima verba* of Mr. Ersley. "Let experts work out the processes, and when they have made a success of them it is time enough for the average photographer to take them up!"

I am rather wandering afar from my subject proper, which is just now the Convention here, whose meeting has just closed. If the "average photographer" would take to heart the retiring President's words, and act upon their spirit, our science would be greatly the gainer. "Mr. W. E. Debenham has stated, and Mr. C. H. Bothamley has corroborated the statement, and my wish is to emphasise it, that there is in our ranks a sad want, an almost total absence of scientific methods of research and logical report of our investigations. . . . We jump at conclusions without safe ground to jump from . . . papers such as we read and write would never be accepted or attended to by societies cultivating any other science, as far as I know." How true! Without arrogating to myself any superiority, indeed, I would rather liken myself to the Publican, and ask for mercy for my own sins, I shall not be alone in saying, I blush for some of the papers I see in print in some of the photographic journals. Conspicuously apart from such were some of our Convention papers. May I instance Mr. Bothamley's own? Without entering into any polemical remarks, I cannot help being struck with

the real usefulness of such a paper, and with the amount of real, honest, carefully conceived work it bears witness to.

There were capital papers upon lenses, too. It would be interesting to know if any one can explain why some malign fate generally seizes upon whoever starts writing upon the peculiarities of the human eye. Mr. Dallmeyer knows something about optics, and yet we find him stating that "the eyes cannot take in without movement more than from a quarter to a third of the 180°." The fact is, the eyes take in an angle very closely approximating 180°, and a single eye no greatly inferior range. *En passant*, it may be said that his theoretically perfect instrument—a pinhole camera with the section of a mathematical line for an aperture—is a hard nut to crack; for a line is a two-dimensional imagination, and if one dimension-length is removed, it is difficult to conceive the remaining one breadth "without breadth," and possessing no magnitude to produce diffractions. Then, again, still keeping to the eye question, we have our old and respected mentor, Mr. H. P. Robinson, writing, "It has been said that the eye only sees about five per cent. of what is before it; this is true in a double sense, but physically the eye only sees an angle of five degrees at one time," &c. Now, I have already stated above that the eye embraces an angle of not very far from 180°, and the experience of any one will tell him that if the space embraced by five degrees be excluded from the field of view there is left behind neither a black, white, or grey space devoid of outlines, as would be the case under Mr. Robinson's contention, so far as to the literal meaning of the words. If, however, they are to be improved upon by inserting the phrase "with distinctness" before the word "sees," there is equal error, for five degrees is greatly in excess of what can be seen at one moment by an immobile eye.

There was in Mr. Bothamley's paper one sad omission, he said not a word upon their power of weather prophecy! If any one will turn to page 541 of this JOURNAL he will find an account of the discoveries of Dr. Zerger, of Prague, who finds that photographs of the sun, taken on orthochromatic plates, furnish a means of predicting by more than twenty-four hours the approach of tempests, hurricanes, earthquakes, &c. It may be confidently anticipated after this that their next performances will be the predicting the future of individuals of the human race. It was very interesting to read about the instantaneous photograph of a dog climbing a tree. Does a dog when it climbs a tree always need a quick exposure? We learn that in Australia the rabbits have taken to tree climbing. An interesting pendant to the dog picture would be a rabbit similarly employed.

FREE LANCE.

CONVENTION NOTES.

Birmingham has held aloof from the London Convention. This is to be regretted, for *some* of the Council, at any rate, entertain a lively sense of the trouble and expense the Birmingham brethren put themselves to in order to make it the success it undoubtedly was last year. Into the financial troubles to which this coolness is mainly attributable we do not here care to enter, but we desire to record our conviction that they then did what, in their estimation, was best for the furtherance of the interests of the Convention.

When London was announced as the *locale* of the Convention, it was enthusiastically believed that the Queen would *certainly* open it. Failing this, some other member of the Royal Family would be only too pleased to do so. But when it "came to the scratch," Royalty was inaccessible. The Lord Mayor was appealed to, but he declined, and of all the phalanx of great men, embracing dukes, archbishops, presidents of learned and other societies, and men of scientific and artistic renown who were paraded as "Patrons," not one could be got! These all held aloof, even to the extent of gracing a single meeting with their presence. The moral of this is: let future Conventions stand on their own dignity, and not play the part of toad-eaters or sycophants to those who happen to have great names, and who estimate at its proper worth such servility and obsequiousness. Photography is quite able to stand its own ground upon its own merits. Derby, Glasgow, and Birmingham did the thing right royally without fawning; why should London have been so abjectly parasitical?

Several new departures were made this year. One, which demands first attention, is the confining of the members of Council to residents in, or in the vicinity of, London. This is probably the right and proper thing to do, but what then becomes of the organization of the concern as being of the United Kingdom? Would it not have been at least decent that some few, at any rate, of those who reside in other parts of the United Kingdom than London should have been placed upon the Council? And from the way that these London members were read out from the chair and carried, may it not give rise to the suspicion that the Council is self-nominated and self-elected? We know quite well all that can be advanced relative to electing a Council who, residing in one place, are able to attend all its meetings. But what then of some four or five members not yet elected, and who are to be residents of the next place of meeting, or its vicinity? are they supposed to be able to run up from Chester every now and then to attend the meetings of Council in London? If the organization is to be truly national, common policy demands that those on the Council shall consist of members selected from localities other than London, even although it may be difficult for them to attend every or any meeting.

The members proposed and passed as Councillors are—we give them in alphabetic order—Messrs. W. Bedford, Bridge, C. Beck, Cembrano, Cowan, Clifton, Dallmeyer, Dresser, Davison, S. H. Fry, Friese Greene, Haddon, Haes, H. M. Hastings, Levy, Mackie, Pringle, Samuels, Taylor, Wellington, and Webster. Four more to be added from Chester. Of these we know that one at least has given orders that his name be erased. A separate Treasurership has been abolished, and this office is, for this year at any rate, to devolve upon the Hon. Secretary, Mr. Briginshaw, who most certainly can never be said to have allowed private interests to interfere in the way of the public good.

The attitude of the leading London 'professional' photographers towards the Convention is difficult to understand. Making full allowance for the merely trade, in contradistinction to the technical, interest so many of them are credited with taking in their profession, one might have expected that from motives of policy alone they would have taken at least a seeming interest in it. But in these dull times the five-shilling fee for membership may be a consideration, especially when one could have access to any specially desirable meeting on payment of one shilling.

More anomalous still is the attitude of some who allowed their names to be placed upon the Local Committee, yet who never attended a single meeting, or even, if we are correctly informed, became members of the Convention at all.

The begging of papers from friends to be read at the Convention is largely a farce, seeing that the majority of such papers cannot by any possibility be read, but must be "taken as read." Much better confine this department to at most two good lectures, and devote the remainder of the week of meeting to that for which it is much better adapted, viz., pleasant outings and recreation. It is a small compliment to those who prepare long and, doubtless, interesting papers to relegate them to the limbo of what is so well termed a "massacre of the innocents." Who that has been subjected to this fate will risk its repetition?

With what a wondrous display of zeal, although not according to knowledge, did Mr. Andrew Pringle, the late President of the Convention, try to trip us up in *re* the publication of certain two papers! But that we know that cowardice is no part of a Scotchman's character we should have attributed to this feeling the fact of his sending his letter to the other journals, in which he was certain of holding his ground for a week at least, while carefully abstaining from sending it to us, in the moral certainty of his being stampeded down. Connected as an editorial writer with another journal, he loyally did his level best, whether under compulsion by his chief or not it matters not to us, to try to make it appear that we alone were the sinners in regard to publishing two papers in addition to his own (relative to which no offence was taken). But, alas! for his imperfect acquaintance with

photographic serial journalism, he closed his eyes to the fact that the offending papers also appeared in the *Photographic News*, the editor of which journal says he published them under official instructions, or to quote his own words in reply to Mr. Pringle's letter:—"The papers were published in these pages because on the Tuesday evening the *Honorary Secretary to the Convention handed us the proofs in the hall, and said that the arrangement with the photographic press had been rescinded, consequently we might publish them without delay.*" It is a pity, for the sake of Mr. Pringle's reputation, that he had no Mentor at his elbow to check him when in his eager zeal, presumably to obey the injunction of his journalistic chief, he made a rush at the ink bottle and had a dash at THE BRITISH JOURNAL OF PHOTOGRAPHY. We said the resolution had been rescinded, hence our publication. We gave no names, preferring to take the blame, if blame there was. Our contemporary is more outspoken; but what is the sum as regards the estimating of the action of the late President?

What a splendid display did the Eastman Company make at the Convention Exhibition! They had everything, as regards size, from the small Kodak to truly magnificent enlargements, and they also had a most excellent display of apparatus of all kinds. Messrs. B. J. Edwards & Co. had also a fine display of their specialities. We are favoured by Mr. Hindley, of the firm of Mr. Jonathan Fallowfield, with an admirable collection of groups taken by the excellent Fallowfield Facile Detective, which shows its perfect adaptability for pictures of this class. But of the general collection of apparatus or pictures, historical and artistic, exhibited by Messrs. Werge; Watson & Sons; R. W. Thomas & Co.; Houghton & Son; Gotz; Taylor, Taylor, & Hobson; R. & J. Beck; S. Fry & Co.; Noakes & Son; and Swift & Son, it is almost needless to speak. Each firm showed its latest and best work, of which it would be impossible here to speak at such length as to do them justice.

THE CONVENTION.

[THE following papers were contributed to the Convention, but, for want of time, were not read.]

FOX TALBOT—HIS EARLY EXPERIMENTS.

By FRIESE GREENE.

MR. TALBOT was the only child of the marriage of William Davenport Talbot, of Lacock Abbey, in the county of Wiltshire, with Lady Elizabeth Theresa Fox-Strangways, eldest daughter of the second Earl of Ilchester. He was born at Melbury, in Dorsetshire, the seat of the Earl, on the 11th of February, 1800. His father, William Davenport Talbot, died July, 1800, when his son was only five months old. His mother married, secondly, in 1804, Captain, afterwards Rear-Admiral, Charles Fielding, by whom she had two daughters—Caroline, Countess Dowager of Mount Edgcumbe, and Horatia, late wife of Thomas Gaisford, Esq. Mr. Talbot was educated at Harrow, where he displayed marked abilities at a very early age, for in a letter written by Dr. Butler to Lord Winchelsea in December, 1812, occurs the following paragraph:—"Little Talbot goes on capitally; he has just finished his trial for the fifth form, and has done himself credit; I am really distressed at removing him at so early an age into the fifth form, but if his acquirements are beyond his years, how can I help it?" His acquirements were beyond his years, and the ordinary school work soon became insufficient to satisfy his intellectual powers. He took up chemistry, and one of his experiments resulted in an explosion, which alarmed Dr. Butler for the safety of his house, and made him declare that he could only allow the theory of chemistry to be studied at Harrow. Dr. Butler himself was fond of chemistry, and very kindly offered to lend his pupil any of his books on the subject. The prohibition was, of course, respected, but the ardent student arranged to carry on his future experiments in the shop of a neighbouring blacksmith, and thus continue, by his own manipulation, to illustrate and test the statement contained in his textbooks.

On leaving Harrow, he read with a private tutor, and then entered Trinity College, Cambridge, where, in 1820, he gained the Porson prize for Greek verse. He graduated in honours in 1821, being twelfth wrangler and second chancellor's medalist. About 1821 he left England, travelling, not as an idle loungeur, but with the aims of a scholar and man of science; his education and bias of mind qualified

him for observation and study. His love of plants and flowers remained with him until the last, and was exhibited in his green-houses at Lacock Abbey. He appears to have always been in pursuit of knowledge, in pure mathematics, in physics, and in chemistry; for the range and character of his researches, reference may be made to many papers in scientific journals from 1836 to 1847. The attention of the leading men of science was naturally attracted to the successful researches of Mr. Talbot, and he was elected a Fellow of the Royal Society on the 17th of March, 1831. The Royal medal of the Society was awarded to him in 1838 for his papers, published in the *Philosophical Transactions* for the year 1836 and 1837; in 1842 the Rumford medal was awarded to him for his "Discoveries and Improvements in Photography." His other researches in science are less popularly known than his brilliant discovery of a method of fixing the image of an object in the camera obscura, in the completion of which the art of photography consists. This invention was not a mere chance result of a chemical experiment; on the contrary, it was a calculated series of results. It was a profound application of optical and chemical knowledge to the solution of definite problems, the solution of each being one step towards the grand result. You can see this by what Fox Talbot says of the invention of the art of photography in the first volume of *Pencil of Nature*, published by Longmans, Brown, Green, & Longmans, 1844. I have the original copy here, so any member who wishes to look at it can do so, and he will find it very interesting, especially the pictures, which are very good, considering they were finished so many years ago. I have read it over and over again, and always find some new idea started, when you compare photography as it was at that time and photography as it is at the present time. Well, this is what he says on the third sheet:—

"One of the first days of the month of October, 1833, I was amusing myself on the lovely lake of Como, in Italy, taking sketches with Wollaston's camera lucida, or rather, I should say, attempting to take them, but with the smallest possible amount of success, for when the eye was removed from the prism, in which all looked beautiful, I found that the faithless pencil had only left traces on the paper melancholy to behold; after various attempts, I laid aside the instrument and came to the conclusion that its use required a previous knowledge of drawing, which unfortunately I did not possess. I then thought of trying again a method which I had tried many years ago; this method was to take a camera obscura and to throw the image of the objects on a piece of tracing paper laid on a plain piece of glass in the focus of the instrument, on this paper the objects are distinctly seen, and can be traced out with a pencil with some degree of accuracy, though not without much time and trouble. I had tried this simple method during former visits to Italy, in 1823 and 1824, but found it in practice difficult to manage, because the pressure of the hand and pencil upon the paper tends to shake and displace the instrument (insecurely fixed, in all probability, while taking a hasty sketch of a roadside, or the view from an inn window), and if the instrument is once moved it is almost an impossibility to get it back again so as to point truly in its former direction; besides which, there is another objection, viz., that it baffles the skill and patience of the amateur to trace all the minute details visible on the paper, so that, in fact, he carries away with him little beyond a mere *souvenir* of the scene, which, however, certainly has its value when looked back to in long after years; such then was the method which I proposed to try again, and to endeavour, as before, to trace with my pencil the outlines of the scenery depicted on the paper; and this led me to reflect on the inimitable beauty of the pictures of nature's painting which the glass lens of the camera throws upon the paper in its focus—fairly pictures, creations of the moment, and destined as rapidly to fade away. It was during those thoughts that the idea occurred to me—how charming it would be if it were possible to cause these natural images to imprint themselves durably and remain fixed upon the paper. And why should it not be possible? I asked myself."

Now here, you see, is the genius of Fox Talbot, the question why and the determination to know at the particular moment; and he says, if you read on, "I made a careful note with such experiments as I thought would be most likely to realise it if it were possible;" so the knowledge of chemistry which Talbot must have had was the main link which brought floating philosophic visions to reality. So in January, 1834, Fox Talbot procured some nitrate of silver (strange to say we have not found a substance yet to better nitrate of silver for our principal processes, but I am under the impression it won't be long before nitrate of silver will be put aside and something cheaper will take its place); he made a solution, and with a brush spread some on a sheet of paper, he put it in the sunshine and was disappointed to find that the effect was very slow in comparison to what he anticipated. What would he say now if he were alive? In one thousandth part of a second you can get a picture full of detail, which at that time would take a man a lifetime to draw, and then not so full of minute detail and so true to nature. Then his next experiment

was to wash the sheet of paper with a strong solution of salt, and when this was dry it was washed again with nitrate of silver. Of course, chloride of silver was then formed in the paper; but he found this was not much quicker, but he noticed where there was not much salt it darkened much quicker, so he tried a weaker solution of salt, and it immediately manifested a far greater degree of sensitiveness. Here he established beyond doubt the important fact that a less quantity of salt produced a greater effect, and no doubt many of us here, in experimenting, are as near important discoveries as he was with the first solution of salt, but not the fortune to have a weak spot to notice, and if we have, we have, perhaps, not the power of perception to notice it. Fox Talbot not only found out the quickness through the spot, but we find his first fixing solution was a strong solution of salt to stop the further action of light upon sensitive paper. Now Mr. C. H. Talbot, his son (who I have the honour of knowing), has some of these pictures in good preservation which were done by his father in 1835, signed and dated. He very kindly brought a series of these before the Bath Photographic Society, and I had the pleasure and good fortune to have a good look at them, and I can assure you I was immensely surprised to find these early results in such good condition, especially taking into consideration the camera and lens and the difficulty of obtaining chemicals at that time for working photography.

Now it took an hour or two to procure a picture at that time, so he tried no end of experiments to make the paper more sensitive; and here he says, during his experiments, how necessary it was to trust to nothing but actual experiment. He tried repeated alternate washes of salts and silver, and, using it in a moist state, so he reduced the exposure from an hour to ten minutes. These being Fox Talbot's important discoveries in 1835, I wonder he never brought them before some society until Daguerre made known to the world his important discovery; but then at that time there was not in England an Arago who kept on extolling Daguerre's discovery to the Assembly of Science, which surprised the whole scientific world; besides, Fox Talbot was of a modest nature, and his results were achieved only by steady work continued year after year. Strange to say, all the principal processes used now, such as transparent paper, films, &c., are the outcome of Fox Talbot's experiments. Here are some of his first paper negatives, which his son kindly gave to the Bath Photographic Society; and here are some more which Mrs. Calvert Jones kindly lent me, taken by her husband and Fox Talbot in the early days. Mr. Calvert Jones was the first to whom Fox Talbot taught his process, and he was a personal friend as well. The unique box of Daguerreotypes was also taken by them. Now I want you to look at these negatives carefully, and as they are passed round give your honest opinion upon them, and see if you do not come to this conclusion, that though we have advanced so much it seems so little. There is also a complete set of *Pencil of Nature*, which is very rare and valuable. Look how well some of the pictures have kept—and nearly fifty years old!

In spite of high birth and good means, Fox Talbot was one of the few men who devote themselves to scientific research during the greater part of their lives. Fox Talbot's genius was very versatile, for he did good work in spectrum analysis, and, with Rawlinson and Hincks, was one of the first to decipher the cuneiform inscriptions brought from Nineveh. We also owe to Talbot the use of albumen employed for printing photographs; and on September 20, 1840, he discovered the latent image (which, by-the-by, none of us understand yet), and the mode of its development, which altered the whole system of his work. During the British Association's visit to Bath last year I had the pleasure of seeing the place where Fox Talbot's first experiments were tried, and recognised the places in the pictures which are here; and during the time I was admiring the noble mansion a profound sense of feeling and respect for Fox Talbot, the English father of photography, came over me.

He died at Lacock Abbey on the 17th of September, 1877, full of years and honour. It is greatly to be regretted that no public memorial has yet been raised to his memory; why, at the French Society, when I was at Paris a fortnight ago, they had three busts of Daguerre in the room. By Fox Talbot's discovery we are getting to love the beautiful symmetry of nature's secrets; even in the invisible portion (to the eye) of the insects we now by the aid of enlarged photographs trace the beauty and form—a love and appreciation which was repulsive to us before: it seems as if we have a new world to investigate, many great truths are half known and half enjoyed for centuries; the means and the wish to know the other half is the essence and the substance of all great discoveries. Now photography is launched upon the restless ocean of the human mind we can safely calculate for advancement which will calm down mysteries and bring things home to us as they really are. Photographers should always be in a good humour, for people always put on their best look

to be photographed, and the reflection from these charming faces we see should be sufficient in itself to make us always happy. Besides—

"Photography is like magician's charm—
We nurse the absent, in affection warm
Present the distant, and retain the dead
Shadows remaining, but the substance fled;
For faces vanish like the dreams of night,
But live in portraits drawn by beams of light.
Exquisite Nature caught in changing dress;
Motion in photography appears at rest."

PAST AND PRESENT.

By W. M. ASHMAN.

WHEN the gigantic strides which photography has made amongst the arts, and the enormous advantages it confers on mankind at large, are considered, it is really a matter of surprise that until recently such a comparatively small proportion of literary work should have served for the dissemination of its marvellous capabilities. But this apparent state of quiescence as regards the development and spread of photographic knowledge is fast melting away before the fierce heat of popular enthusiasm now to be met with on all sides, and in every civilised community societies formed for the express object of advancing photography are making great headway: the number, which increases at an astonishing rate, can now safely be estimated at a hundred in this country alone, there being hardly a centre of importance where a band of the brotherhood does not exist. It would be difficult to comprehend the amount of energy displayed by active members of these many societies, or appraise the value of this work, only a tithe of which gets recorded in the respective societies' archives, to slumber indefinitely within the recesses of the Secretary's minute-book of proceedings. The process of referring to such an *omnium gatherum* being at all times tedious, and owing to its limited scope in a great many instances proving of but dubious efficacy, outside publication of the sayings and doings of individual members has grown to be a necessity to photographic society existence, and one which it would not be difficult to show has sprung up in a ratio with the growth of photographic society discussions rather than to the popularity of any particular quantity or quality of photographs, such as are produced on a strictly commercial basis.

Looking back through the pages of our brief history, to the incipient stage, if we may so phrase it—to the period when Fox Talbot, Herschel, Brewster, Hunt, Reid, Ponton, and many others in this country, contrived in a brief space of time to introduce to the scientific world a constant series of discoveries of more or less immediate importance—we find that in many instances a very meagre record appears to have been kept. It may be that little was then thought to be necessary which did not bear directly upon the process occupying the experimentalist's immediate attention; but who can judge of what recorded experiments may or may not at some future date be of intrinsic value, and perhaps be the means of stemming the progress of an over-ardent patent seeker? Indeed, owing to the scarcity of reliable information on several matters it has, in so short a period as a trifle over half a century, become no easy task for the historian to assign to our English experimentalists their due share of honour for the discoveries they made. A writer of history is dependent upon former works for much of his narrative, therefore, should the material he has to deal with be incomplete, and there are doubts concerning the accuracy of the earlier publications, future students are almost certain to be led into error. In the pre-journalistic days of photography we learn that the record of progress was restricted to stray paragraphs, which from time to time appeared in the public press, or the printing of certain papers on photography in *Philosophical Transactions*, the authors having read them before the Royal Society. These, together with a few works written by well-known experimenters of the time, whose names have since become household words, were the available sources of information, and based upon this material the English portion of the early history of photography has been built up. There yet remains to be brought to light investigations recorded only in note-books, some of which are known to be carefully preserved, awaiting a fitting and convenient opportunity to be placed in history. It is fortunate that as time passed on one or two societies sprang into existence whose business was the advancement of photography as a separate and distinct branch of science, and the result of their work was published by themselves. The information, so meagre at that period, and so much in request, led to the founding of journals devoted exclusively to the interests of photography from a scientific as well as a commercial point of view, and henceforward the advancement of photographic knowledge and

the elucidation of all that pertains to the fundamental principles underlying processes has been steady and quite unmistakable.

At this period, however, the general interest exhibited in the study and progress of the art, as distinguished from the novelty created, may very well be gauged by the number of societies existing for the mutual interchange of ideas and for the general advancement of photography. The possibility of producing a pictorial representation by the aid of light and the alteration of some chemical compound was known early in the *thirties*, and abroad at a still earlier date. Yet it was not until about twenty years afterwards, in 1852, that the first photographic society was formed, followed in 1853 by the present Photographic Society of Great Britain, then known as the London Photographic Society. Manchester came next in 1855, and ranks second in point of venerable activity at the present time. The South London Photographic Society, founded in 1859, did most excellent service, but upon the death of the President, the Rev. F. F. Statham, in 1884, fell into almost complete lethargy, and, as a consequence, after some twenty-five years' work, succumbed from inanition.

Running down the list as published at the time, we find between 1860 and '70 that seven more were formed: the Amateur Photographic Association, also societies at Sheffield, Edinburgh, Glasgow, Liverpool, Cheltenham, and Oldham. In the following ten years seven others were added: Bristol and West of England, 1871; Photographers' Benevolent Association, 1873; Sheffield, 1876; Photographic Club, Dundee and East of Scotland, Photographic Society of Ireland, 1879. Now the influence of rapid dry plate photography becomes apparent, four societies within our own border having been formed in the one year, 1879. Since the advent of 1880 to the present time the number of societies started in this country, and busily engaged, may be estimated at no less than eighty, about a dozen and a half of which were established last year. The majority of these many centres of enlightenment are very active ones, ranging in membership force from twenty-five as a minimum to considerably over four hundred as a maximum. The present strength of the membership roll of the Convention of the United Kingdom I do not exactly know, but judging from the large and representative committee elected to carry on the work this jubilee year of English photography, one is naturally led to the conclusion that the Society is as numerous as it is important, and, further, that the great energy displayed by those gentlemen who have undertaken to guide the ship will call forth the hearty response which such unselfish labour deserves. The objects of the Convention—at least, such as I imagine them to be—are so distinct from those of the general run of photographic societies that I am led on the present occasion to leave out of this short paper matters of a purely technical nature, such as may be regarded as the legitimate business of any one of our hundred or more societies, and to crave your patience while I state a case which many are agreed ought to be dealt with at once.

I have already mentioned certain familiar names in connexion with the beginning, so to speak, of that photography we are so proud to be now associated with, but to relate anything like a chain of circumstances, or to dilate upon those original researches which contribute so much towards the present position held by photography, would not be fitting here, where so much work is contemplated in a very brief period. Every one will readily admit that we owe a deep debt of gratitude to our English fathers of photography, a debt that mere words introduced into papers and manuals by way of preface does not adequately recognise, since such expressions are those only of the individual authors, though, let us hope, they record the general sentiments of us all. We who are situated in the provinces or abroad are looking forward with interest to the result of this meeting of the Convention in 1889 at St. James's Hall, London, where the jubilee of the discovery of English photography is to be celebrated. Several celebrations termed "jubilee" have already taken place in connexion with our art, but have any steps been taken to establish a permanent testimony to our great benefactors? Monuments have been talked of in honour of William Henry Fox Talbot as a set-off against those erected in France to honour the illustrious Frenchmen, M. Daguerre and M. Nicéphore Niepce, but the wisdom of building monuments of such a kind is doubted by many who would gladly help in some other scheme to perpetuate the esteem we of the present generation have for those veterans who have gone before. It would be presumptuous for me to come to the Convention with a cut-and-dried scheme and ask you to give me your support in carrying it out, but I will ask you in the interests of photographers to consider whether this Convention week is not an opportune time to appoint a committee with power to bring forward a definite plan, and submit the same for general approval as early as possible. In my own opinion Fox Talbot stands first in the importance of his successful researches. Some of his photographs, produced as far back as 1835, are, I believe, preserved at Lacock Abbey, Wilts, by his son, but these historical

treasures have been publicly exhibited at a photographic society's meeting, held in the early part of the present year at Bath. An album of calotypes produced by the inventor has also been placed on view in the hall by permission of the society referred to, and I am sure those who have an opportunity of examining these valuable prints will be struck both with the excellence of selection and the degree of permanence they exhibit.

Mr. Friese Greene, who has been entrusted with the album, will doubtless in his capacity of delegate deal with this matter more fully than it is my purpose to do, for other names also await their share of recognition. Mungo Ponton is thought by many to be as deserving of monumental adoration in Scotland as the great Frenchmen in their own land, or Talbot in this country. Sir John Herschel's researches were by no means meagre; whilst to Robert Hunt, Claudet, Goddard, Sutton, and others, due prominence ought in justice to be given. To erect a statue in honour of every scientist who has discovered a photographic process is out of the question, but to found an institute for the advancement of photography may seem practicable to commemorate this period of our history. There is ample work to do, and if properly managed such an institution might prove useful in many ways. Within its walls the future photographer might find the portraits of the fathers of photography, a record of their experiments, and examples of their work. Starting with such material, later inventions, improvements, or discoveries, would doubtless follow in proper sequence, and something like a national institution would be the result. Whatever is done to commemorate the early work in photography could not have a better start than at this Convention gathering of photographers, representative of all the different photographic societies of the United Kingdom, and the numerous industries which the birth of this art has given rise to: at least, such is the opinion held by yours fraternally,

W. M. ASHMAN.

THE PHOTO-MECHANICAL PRINTING METHODS AS EMPLOYED IN THE JUBILEE YEAR OF PHOTOGRAPHY.

By THOMAS BOLAS.

LITTLE did the first makers of sun-pictures imagine that, within the short time of fifty years from the time of their work, what one may term solid metal photographs would be running to and fro on the "coffins" of our largest and quickest printing machines, and from them impressions, just in all gradations of tint, would be turned off at the rate of something like fifteen hundred an hour. Such is, however, the case at the present time, and probably there is scarcely a typographic printer in London who has not worked from the phototypic blocks now so common.

Though phototype blocks represent in the aggregate the form in which photo-mechanical printing surfaces are most commonly met with and used, it is desirable to take a brief survey of the most important printing methods which come under the category of photo-mechanical methods, and we may begin with—

PHOTO-LITHOGRAPHY.

In the method which is most common, a sheet of paper coated with gum, albumen, or gelatine, containing bichromate of potash or ammonia, is exposed to light under a clearly defined and intense line negative, and after exposure the sensitive surface is thinly and uniformly coated with printers' ink, or a special ink of analogous composition, but made up with less pigment than is contained in the usual ink. The inked paper being now immersed in water and the surface very gently rubbed with a soft and long-haired camel's-hair brush, the ink becomes removed from the parts where the bichromated colloid has been protected from the light by the opaque parts of the negative. The bichromated colloid where acted on by light loses its power of softening in water and retains the ink; where not acted on by light it softens in the water and the ink loses its hold. The image with printers' ink thus prepared is called a photo-lithographic transfer.

The following details are sufficient to enable any photographer to make a transfer in fatty ink ready for the lithographer to "put down" on the stone, and print by the ordinary lithographic method, which method need not be described here, as it is in no way photographic, and no special treatment is required in dealing with a transfer made by photography.

A sheet of plain paper is floated on a warm solution of gelatine (containing six per cent. of gelatine), and it is then hung up to dry. When dry it is insensitive to light, and it may be kept any length of time without injury. To make it sensitive to light it is soaked for a few minutes in a solution of potassium bichromate, which contains about three and a half per cent. of the salt, and it is hung up to dry,

but this time in a dark room, or in a room illuminated by yellow light. When dry, it is ready for exposure under the negative.

For a short time it is left soaking in water, and gently brushed on the inked surface with a wet camel's-hair brush. The ink gradually comes off, but in order to save time it is often desirable to employ a little warm water, and, at the same time, continue to use the brush. Now, the end of the matter is, that the printers' ink becomes removed from all those parts of the paper which were not exposed to the action of light, and an image in fatty ink is thus obtained on the gelatinised paper. From this the excess of water is now removed by means of blotting paper, and the print, inked face downwards, is laid on a clean and slightly warm lithographic stone. The stone and paper being now passed through the press, the paper adheres firmly to it, but on moistening the paper with a sponge it becomes easily removable. When stripped off, the fatty ink is fixed on the surface of the stone, leaving a perfect but reversed image thereon. All is now ready for the lithographic printer, who gums and etches the stone, as a preliminary to the ordinary printing process.

Instead of putting the photo-lithographic transfer down on a lithographic stone, it may be put down on a zinc plate, and the plate can be printed from, if treated exactly as the stone was treated.

In its usual form, photo-lithography is only adapted for the reproduction of line subjects, or subjects in extreme black and white, and various attempts have been made to render it available for the reproduction of the gradations of a negative taken from nature. By a modification of Asser's starch process it is easy to get results which are excellent renderings of half-tone as a grain or stipple. A sheet of blotting paper is covered with ordinary flour paste, containing eight per cent. of flour. The paper having been coated, it is next smoothed with a soft badger brush, and when dry the paper is soaked in a three and a half per cent. solution of potassium bichromate, to make it sensitive to light. This piece of sensitive paper being placed under a negative, and exposed to the light of burning magnesium for a few minutes, or to daylight for a longer time, soon becomes tinted with a brown colour where acted on by light, as you see. The light brown print is next soaked in cold water, in order to remove the unaltered portion of the potassium bichromate, after which it is dried and ironed with a warm flat-iron. This last operation is to harden the coating. We now put the ironed print into water, take it out, lay it on blotting paper, and dab on printers' ink with a stiff brush. The ink adheres to those parts where the bichromated paste has been made insoluble by the action of light, and it refuses to adhere to those parts where the paste remains soluble. In this way a fatty transfer is obtained, which shows all gradations of a negative taken from nature, not, however, as a true half-tone, but as a grain or stipple well adapted for transferring to stone or zinc. As a fine image of this kind is liable to get clogged up when printed from stone, it is better to transfer it to a plate of zinc, and to make a typographic block from this by the etching method.

PHOTOTYPIC BLOCKS.

A fatty ink transfer, similar to that which is commonly put down on a lithographic stone, can be transferred to a smooth and clean zinc plate, and the ink firmly adheres to the zinc, just as it would to the stone. A treatment with gum now protects the clear parts of the zinc plate against the adhesion of printing ink, and the application of the ink roller adds more ink to the fatty image already on the surface of the zinc plate. So far the process resembles the photo-lithographic process; but, instead of printing from the zinc plate, powdered resin is dusted over it, in order to give firmness to the fatty image. The zinc etcher next very slightly warms the plate to make the resin and ink partially blend, and then puts it into dilute nitric acid, containing one part of acid to about forty parts of water. Here it remains for about three minutes, during which time the acid dissolves away those parts of the metal which are not covered by the waterproof coating. The covered parts now stand slightly in relief, but only very little, and if we were to continue the etching without further preparation, the acid would gradually undermine the lines, and the image would be lost. Now, the undermining action of the acid can easily be prevented by washing the plate, drying it, and then heating it sufficiently to just melt the resin. Under these circumstances, the melted resin blends with the printers' ink, and runs down over the sides of the little ridges left by the etching, and protects these sides from the further action of the acid. Having done this, it is well to gum the plate once more, ink again, dry, and dust with resin before proceeding to another etching. This second etching may be done with stronger acid than the first, say one of nitric acid to thirty parts of water, and it may be continued longer, say for six or seven minutes, and when this second etching is finished, the series of operations must be repeated until sufficient depth is obtained, care being taken that the melting of the resin is only carried far enough to allow it to flow just over the

sides of the relief left by the previous etching. In ordinary cases, ten etchings are enough to give the necessary depth, but in the case of important work it may be necessary to give twenty or thirty very slight etchings in order to obtain the same depth, without endangering very fine lines or details.

The process of zinc etching has been largely employed for the production of typographic blocks from fatty transfers, either drawn by hand or printed, and this phase of the process bids fair to compete successfully with the art of wood-engraving.

There are other methods of producing phototypic blocks, among which may be specially mentioned the method which is founded on the swelling of gelatine.

By the following modification of the swelled gelatine process I have succeeded in overcoming many of the difficulties of the methods already published.

We start with some clear sheet gelatine about one-thirtieth of an inch in thickness. This can be prepared by drying a layer of gelatine solution on a sheet of waxed glass, or it can be purchased from Mr. Cornelissen, of Great Queen-street. To make this gelatine sensitive to light it is soaked in three and a half per cent. solution of potassium bichromate until it becomes flaccid; it is then laid on a piece of clean glass, and the excess of solution is removed by an application of the squeegee. The plate bearing the wet gelatine is then placed in a warm and photographically dark place to dry, and when dry it can be easily separated from the glass by raising one corner with a penknife. We obtain in this way a flat sheet of sensitive gelatine, having a smooth surface and all ready for exposure under the negative, and this exposure may last from ten to twenty minutes in sunshine, or a correspondingly longer time in the shade.

We now take the exposed film and put it into water to soak, and those parts which were protected from the light begin to swell immediately, while the exposed parts refuse to swell in the water. The soaking should last several hours, especially when the temperature is low, and when the gelatine has soaked the necessary time we make a cast from that. For this purpose we lay the wet gelatine film on a piece of glass, exposed side upwards, and squeegee it down as before—you see that it adheres to the glass quite easily—and after having made it surface-dry by dabbing with a soft cloth, a little oil is applied, and distributed over the surface. Now that the excess of oil has been removed by a soft cloth, we pour on plaster of Paris to a thickness of about an inch, taking care to remove any air bubbles by the application of a camel's-hair brush through the liquid plaster.

This plaster will take about ten minutes to become solid, and if we violently tear the plaster and the gelatine apart, the fine details of the cast are almost sure to be damaged. But, instead of doing this, a good plan is to hold the glass plate in one hand and gently push the plaster cast with the other. Now the gelatine slowly slides over the glass, and finally it will slide quite off, the gelatine still being adherent to the plaster. It is now merely necessary to turn up one corner of the gelatine film and slowly fold it back, so as to draw it off the plaster gently and without fear of damage, either to the gelatine relief or the plaster, just as a lithographer draws a thin paper proof from the stone. The next step is to make a cast in stearine from the plaster, and for this purpose the plaster should be soaked in rather warm water, about 60° Centigrade, and on this soaked and warm plaster a layer of stearine about an inch thick should be cast. The stearine cast is now dusted over with blacklead or bronze powder, and is then put into the electrotyping bath, and when a sufficient quantity of copper has been deposited it is merely necessary to back up with type-metal and mount on a wood block, the work being then ready for the typographic press. If the process I have described is gone through with an ordinary half-tone negative, an exceedingly beautiful electrotpe is obtained, in which the gradations of light and shade are represented by varying degrees of relief. These, or even plaster casts, ought, I think, to have a very good sale, if photographers would only take the matter up. The ease with which they can be made is surprising.

I may mention that, instead of taking a cast from the plaster in stearine, guttapercha may be used, a press being employed to force the plaster cast—which should be in an iron chase—into the soft guttapercha.

The depth of the relief obtainable by the swelled gelatine process is about equal to that of an ordinary visiting card, and where large surfaces of white occur, it is necessary to deepen the plate in these parts. This may be done either by cutting out the metal from the finished plate, or in most cases more conveniently by raising the surface of the mould, let it be wax, stearine, or guttapercha, on which the electrotypic copper is to be deposited. This is best done by holding a stick of stearine or wax in the left hand, and a warm pencil of metal in the other hand, and so holding the wax or stearine as to let a thin melted stream flow down the warm

pencil. This stream is allowed to flow on those parts of the mould which require raising.

ENGRAVING ON METAL PLATES.

We now go back to the first photographic process discovered—that is to say, the first process which gave photographic representations which could be exposed to light without destruction—the bitumen process of the hard-working and patient Niepce. This investigator noticed that the residue left on the drying of certain varnishes became insoluble by exposure to light. About the year 1814 he covered metal plates with a bituminous varnish, exposed them in the camera obscura, and after exposure he subjected them to the action of similar solvents to those originally employed in making the varnish. Under these circumstances those parts of the film which had been exposed to strong light refused to dissolve, while the unexposed parts dissolved, a negative image being thus formed on the metal plate. To convert this negative image into a positive, those parts of the metal which were uncovered by bituminous matter were darkened by the vapour of iodine, and the bitumen was then removed by the use of a more powerful solvent. By the application of a suitable acid to the bitumen pictures on metal, the bare parts were dissolved away, and engraved plates were obtained. Bitumen or asphalt dissolves readily in benzole, and the solution runs freely through a paper filter. The solution should not be quite as thick as collodion. A carefully cleaned copper plate, such as the engravers use, is clamped down on to a turntable. The next step is to flood the plate with bitumen solution, and then to make the table revolve quickly. When it has revolved a few seconds the film will be dry. I know of no other method by which such a uniform and compact film of bitumen can be obtained. After coating, it is well to put the plate aside for twelve hours, in order that the film may become harder. It is then necessary to dust it over with French chalk, to remove stickiness; and after this it is placed behind a transparency and exposed to light. The time of the exposure may vary from twenty minutes to two days.

When a plate has had the requisite exposure, the next matter is to dissolve away that portion of the bitumen which has not been made insoluble by the action of light. Now, benzole is generally too energetic a solvent for my purpose, and oil of turpentine is often not sufficiently active; but by mixing these together you can get any degree of solvent power which you may require. The workman commences by flooding the plate with oil of turpentine, and if this has not sufficient action he pours it off and adds a little benzole; this begins to produce an effect, and enables him to judge as to the amount of benzole which he may safely add to the oil of turpentine. When he has added this quantity, and has washed away all the soluble bitumen from the plate, it is next thoroughly rinsed with water to remove the oil of turpentine. The plate is next placed in nitric acid, so as to etch the lines where the metal is bare.

So much for the line-engraving process of Niepce; but it is worth mention that very perfect half-tone transparency pictures may be produced by means of bitumen. Let us take some pieces of sheet gelatine, or some pieces of talc, which have been varnished on one side with bituminous varnish.

Supposing that the varnished side of the talc or gelatine is placed in contact with the negative, and the light is allowed to shine through it, those parts of the bitumen film which are under the perfectly transparent parts of the negative become insoluble, let us say, all through. Now, those parts of the film which are under less transparent parts of the negative do not become insoluble all through, but a skin of insoluble bitumen is formed on the surface of the bitumen film, this skin varying in thickness according to the amount of light which has given rise to it. Put a varnished and exposed gelatine sheet of this kind into the solvents and note the effect. When the film is made insoluble all through, it resists the action and remains on the talc; but where only a skin of insoluble bitumen exists on the surface of the film the solvents loosen and dissolve the bitumen from underneath this skin, and away it floats. Now you can understand why the bitumen process, in its ordinary form, is only adapted for the reproduction of subjects in extreme black and white, such as line engravings or letter-press. If we wish to preserve the half-tone picture intact we must expose through the transparent medium (talc or gelatine), so as to ensure every part of the insoluble image, whatever its thickness, being in contact with the transparent support.

A picture of this kind is solid, the gradations of light and shade being due to a greater or less thickness of bitumen, and the essential points in producing them are to varnish a thin, transparent medium with bitumen, to expose to light through this medium, and then to dissolve away that portion of the bitumen which has not been acted on by light. The ordinary black varnish sold for backing glass

positives will answer very well, and so will some samples of Brunswick black.

By the method just indicated very fine lantern slides may be produced, as there is an entire absence of texture or granularity.

Plates from which much printing is to be done are ordinarily covered with a thin film of iron, by the electrolytic method, and as the film of iron is extremely thin, it does not in any way interfere with the printing qualities of the plates. When the surface of a plate begins to wear a little, and the impressions show signs of deterioration, the film of iron is dissolved off by means of dilute sulphuric acid, leaving the copper plate as good as ever. The film of iron, although so thin as not to injure the printing qualities of the plate, is nevertheless sufficiently thick to protect the copper from injury in printing. The plate having been freed from the first worn-out film of iron, is once more coated with a layer of iron, and is again ready for use. When the second film of iron is nearly worn away, and the printer approaches near to the true surface of the copper plate, the iron is again dissolved away, and a new coating of iron is put on. According to this system, one really prints rather from a cast of the plate than from the original plate, and new casts are made as required.

I may call your attention to a very simple and expeditious way of making engraved plates from line subjects. Take a photo-lithographic transfer made from a positive, instead of from a negative, as is usually the case. The ground is black and the lines are white; in fact, by far the greater part of its surface is black. It is now laid on a zinc plate and passed through the press. Now, what will be the result? So much of the paper being covered with printing ink, and so little being white, moist, and gelatinous, the transfer will slide over the zinc plate, and we shall merely get a smear. To prevent this, take another transfer similar to the last, excepting that white patches are introduced on it wherever they can be introduced without falling foul of the picture. This is done by painting on the transparency with Brunswick black. On putting this transfer down on a zinc plate it adheres properly, and we have a perfect image on the metal. As the white patches are now done with, we varnish them over, and the zinc is covered everywhere except where the lines of the engraving are bare. The covering on the zinc is now made denser by inking and dusting with resin, as explained, and the plate is then etched by dilute nitric acid. We now clean off the ink, and you see the lines are engraved on the zinc plate. The plate may now be printed from in the copper-plate press, or, as zinc is not a convenient metal for deep plate-printing, it may be reproduced by the electrotype process.

An extremely simple and expeditious method of engraving line subjects upon copper plates is the bichromated albumen process, practised with much success by Gobert and others. A plate is covered with a film of bichromated albumen, and exposed under a transparency, until the whole of the ground—that is, the part not covered by the lines of the transparency—is rendered insoluble. The plate is next washed with cold water, so as to remove the albumen from the lines, after which the etching is effected by an alcoholic solution of ferric chloride.

The following details will be sufficient to enable the method to be carried into practice. One hundred cubic centimetres of albumen are mixed with a solution of two and a half grammes of bichromate of ammonia in fifty cubic centimetres of water, and, after having been well beaten, the mixture is filtered. A carefully cleaned plate of copper is now coated with the mixture, and after the excess has been well drained off, the plate is dried at a very gentle heat, it being retained in a horizontal position meanwhile. The exposure required is by no means a long one, half a minute in moderate sunshine being sufficient in ordinary cases; but this must, of course, be learned by experience. Instead of developing (washing away the unaltered albumen) in plain water, it is better to use a weak solution of aniline red or magenta dye, as under these circumstances the ground becomes tinted, and the progress of the development can be watched. When the plate has been dried, nothing now remains but to varnish the back and edges with an ordinary black varnish, such as the so-called Brunswick black, and to etch. The etching bath is made by dissolving one part of perchloride of iron in five of alcohol, and ten minutes is generally a sufficient time for etching to the required depth.

The method which Major De la Nöe calls *typogravure* is in reality an intaglio process, but the printing is conducted as in the case of ordinary zincography. The details are as follows:—A prepared zinc plate is coated with a film of sensitive bitumen by well-known means, and exposure is made under a transparency or a tracing, so that when development is carried on with turpentine or benzole in the usual way, the lines alone are bare. The plate is now etched with dilute nitric acid (1 to 40) until a depth of about a 250th of an inch is reached, after which the plate is dried, and once more coated with bitumen. The ground is now polished off with a stick of charcoal,

leaving the bitumen in the lines; after which, the plate is gummed and printed from by the usual zincographic method. This process is admirable for map work, although it is obviously inapplicable for the reproduction of subjects with widely extended blacks; and it has the advantage that the lines show no tendency to spread.

Before going any further we may, with advantage, look back at some of the older examples of photo-engraving in half-tone. Excellent work was done by Talbot's etching process over twenty-five years ago. Some examples of work done by Pretsch about twenty years ago are quite sufficient to prove that good work is not altogether a thing of to-day. Among the newer methods, that of Klic deserves special mention. Klic's process is an etching method, the result being a "carbon" print. A copper plate is dusted with powdered asphalt, and the plate is heated, so that the asphalt becomes nearly melted. A negative carbon print is now transferred on to the copper plate, and the plate, now covered with the negative in carbon, is etched—at first by a strong solution of perchloride of iron, which penetrates only the thinnest parts of the picture; then, by a weaker solution of the same salt, the solution etching through the thicker parts. By employing more and more diluted solutions, it is possible to etch through thicker and thicker layers of gelatine, so that only the high lights remain unetched.

Major Waterhouse has been remarkably successful during the past few years in making intaglio plates, and he has published the details of his method. The process is a modification of one introduced some time previously by Geymet, and it is based on the mechanical reticulation or breaking up of the Woodbury relief.

A Woodbury relief is developed upon a plate of silvered copper (but the relief need not be nearly so high as that required for the Woodbury process; in fact, an ordinary carbon print will answer), and when the relief is taken out of the developing water, it is dipped into a solution of potassium bichromate, drained, and dusted over with fine sand—this sand having been previously waxed by being heated in an iron pot, and stirred up with a small proportion of wax. The layer of waxed sand is allowed to remain on the film until it is quite dry, when it is brushed off, leaving the gelatine granulated or pitted all over; the pits being deepest in the thick parts. The plate is now blackened, and a cast is made in the electrotype bath, this cast being the printing plate.

Numerous specimens show what excellent work can be done with this method, and you must remember that Major Waterhouse has not only published full working details, but he has demonstrated the process before several gentlemen interested in the matter; moreover, he has not patented the method.

Some fine examples of the application of photo-engraving to pottery decoration are due to the skill of Mr. F. J. Emery, of Burslem—and one photographic method which this gentleman adopts for the reproduction of pottery designs is of special interest. He coats a plate with sensitive bitumen, puts down upon this surface a transfer from the plate to be reproduced, and exposes to light until the ground is insoluble. Development is now effected with the usual solvents—say, a mixture of turpentine and benzole; only those parts of the ground which were protected by the transfer dissolving. The etching is effected by perchloride of iron.

In connexion with intaglio plate work, special mention must be made of the method of etching copper by means of a solid image of chloride of silver, due to Obernetter, and called by him *Licht Kupferdruck*. A gelatino-bromide image in film form and made from an emulsion rich in silver, is converted in chloride of silver by immersion in a chlorinating solution—a weak solution of bichromate of potash acidified with hydrochloric acid answers well—and this chloride of silver film is laid on a smooth copper plate. The chloride of silver becomes decomposed, the chlorine uniting with the copper and etching it, so that every detail is reproduced as an intaglio. Unless the action is assisted by a weak electric current it is very slow; but when the copper plate is connected with the positive wire of a battery, and the negative wire is connected with a carbon plate placed behind the film picture, the etching of the plate proceeds quickly. The film picture should be moistened with weak salt and water.

(To be continued.)

JACK AND I IN NORWAY.

XII.—EIDE—BERGEN—HOME AGAIN.

WE had been haunted by the stories of no place to sleep and nothing to eat that we were likely to take, and general starvation painted as a likely thing to be met with in many places on the way. I am glad to hear testimony to the fact that this was not so; of course, as was to be expected, in many places the lodging was very plain, but always scrupulously clean,

and the food, if plain, was good, and always nicely served. In all these stations in the country places the prices for board and lodging was very cheap—on an average one could live well on five shillings a day; whenever the place, however, had the importance of a town (a hundred houses would make a town here), and the house of entertainment assumed the importance of an hotel, the prices go up considerably, but in no case would it be called dear. I fancy the increase of travellers is teaching them how to charge.

The continuous run of lake, river, fjord, mountain, and fall excites the traveller so, that a craving for a little rest takes possession of him. You must have felt this sensation in a picture gallery, even when filled with the choicest examples. After a bit you want to sit down and rest and think over what you have seen before you go on again. In such a mood one of our fellow-passengers exclaimed, "I would to heaven this scenery would just stop for half an hour!" And I must confess that such a feeling possessed me more than once on the journey, a feeling as if you had got more than you could take, and that you really needed a little rest to digest it before going on.

Over that part of Norway where we journeyed, photography is in a very backward state, in fact, all the pictures that are to be seen seem to come from Bergen. The trade has not yet attained sufficient importance for any native to venture the starting of a studio in any of the smaller places.

Looking at it from a commercial point of view, the best pictures we saw were landscapes, and the best landscapes were by Beyer, of Bergen. This photographer seems to hold here very much the same position as George Wilson does in Scotland, his pictures being found all over the country, even in the most secluded places where a stray traveller might chance to go. On every station-house all over the mountains, and in the glens, will be found Beyer's advertising boards, blue-painted, with white lettering. He has not got the length of the enamel tablet yet that resists all kinds of weather, for the rain and the storm have obliterated many of the inscriptions on these, and nothing is left but the blue board with a white patch here and there. But after travelling two or three days, you get so familiar with it, it being the only advertisement that is there to attract attention on the way, that you say to yourself "Beyer's board," whether you are able to decipher what is on it or not. Taking his pictures as a whole they are good, and a great many of them must be sold.

We came across some books of views lying at some of the hotels on sale, taken by a photographer from England, but from what we saw of these, Beyer's pictures were very much better: we did not see any good work in portraits even in Bergen. In the shop windows there was exposed any quantity of photographs illustrative of the country and its people, such as portraits with costumes of the different districts, groups of Laps and the like; but all this class of picture was produced in very poor photography.

I think, however, in and about Christiania (which we did not visit) the portrait artist must be more successful, for at some exhibitions here at home I have seen some good portrait work exhibited that had been sent from Norway.

On our return to Bergen, Jack looked up a friend of his of former times, who showed us considerable attention and kindness during our stay. He took us to where we could get the best panoramic views away up by the park, but, alas! our roll gave out on the second view, and we had to be content with the two, for it was a considerable climb, and we did not venture to go again.

We wanted to arrange to go out to Mr. Gade's place and see the Stone Kirke, but when trying to arrange for a conveyance we found that in this town, at any rate, they had got up to the way of charging. I think that they have learned so well, that their charges for hiring is a little in excess of those at home.

Mr. Scarborough (Jack's friend) managed to get us a turn-out on more reasonable terms, and we drove out to Fantoft. There was a fair amount of foliage and wild flowers on the way, and we made a couple of negatives of the kirke, which they say was originally built about the twelfth century—the approximate date is decided by the style of architecture and ornamentation. Being considered of special interest, it is visited by many strangers, and Mr. Gade makes all visitors welcome. We also went out to Neston, a village a few miles out from Bergen, where we went to visit a spinning mill, introduced there as a new industry by Mr. Scarborough. He is of opinion, with plenty of water as the moving power, and labour cheap—as it is here—the speculation should be successful. This mill was a very interesting sight, but the fall at the present point where the mill is placed is supposed not to be a steady one, owing to the snow sources giving out sometimes, so he had just bought a *new steady waterfall* at an outlay of two hundred pounds. A strange fancy buying a waterfall! It put me in mind of Mark Twain going round the country collecting echoes to start an exhibition with.

Mr. Scarborough is a very enterprising gentleman and has various kinds of businesses running successfully. His forefathers came from England, and they have evidently conveyed to him a fair share of the English element of "push." He was of opinion that the Norseman could not advance far, nor fast; he said that they could work well and cheaply, but they failed in management, or the directing of others; besides, the country he thought was not well-suited for commercial enterprise, they were certainly growing in knowledge, but very slowly; but they are poor, and lacked capital to help them on. The countries that were fortunate

enough to possess capital with equal knowledge got before them easily in the race, and he was convinced that the Norsemen stood ten years behind as competitors in the world's trade for the want of money alone.

When here Jack came across a young fellow who had sold him some furs up at Molde the previous year. He turned out to be an actor at the Bergen Theatre, and the fur selling had been done by him when out for a summer holiday. We struck up an acquaintance with him, and he proved one of the most enjoyable of companions. He had a lot of time on his hands, during our stay we used it up for him pretty considerably.

He told me that acting as a profession was a very poor business in Norway, and that the highest salaries paid were very meagre, the principals at their theatre not making more than four pounds a-week. The situations, however, as a rule, are permanent, as the theatre is supported by the State, and it keeps open and salaries are paid regularly whether the receipts of the house itself pay expenses or not.

We had not the opportunity of seeing our young friend performing, but he was certainly a genius at "making up," judging from a series of photographs that he showed us, representations of himself in the various parts he played. The transformation in face and figure were the most perfect things of the kind I had ever seen.

He walked us round many places of interest. Amongst them we visited the German Quay, where were scattered about the largest quantity of dried fish I ever saw in my life, they lay split up and dried hard as mahogany. An axe would be needed to cut them, and even then you could only break them in splinters.

Shiphoads of these fish are continually going out to foreign parts, or to what other countries it would be hard to tell, but it is certainly one of the largest trades of the place, for they lay about in such profusion all along the quay; there must have been hundreds of tons of them. We made a picture of the busy scene, embracing the Hanseatic Museum, an old tumble-down-looking house over the shops forming the corner of the quay. We paid a visit to this museum; in it are stored quantities of antiquities and relics illustrative of the olden time when the Germans inhabited this locality, and lived so exclusively to themselves. In this place they show you a method whereby the beds were all made from the outer passages; this was done so that the domestics need not enter the rooms, the merchants having decided objections to their clerks and other *employés* holding any intercourse with the Norwegian girls. The various rooms and primitive style of living are illustrated—quaint furniture, and curious washing utensils, weapons of war, samples of crude painting, which were considered fine arts then, old books in parchment, and many other curious things which makes it well worthy of a visit. Should it still exist, for it was in a sadly dilapidated condition when we were there, and if they do not look to its renovation, the museum itself, I fear, will soon be a thing of the past.

We visited a cod liver oil factory close by, where we saw the oil being decanted in large quantities green as grass. We were told that the men who worked in the place drank lots of this vile-looking stuff, and took a pleasure in drinking it.

In the same lane as this oil factory we were taken into an old tottering tenement which was used by the fishermen and sailors when they came in worn and weary from the storms at sea. Fire and food, cooking utensils, and other rough comforts were arranged in this place, and it had been used as a house of refuge since the days of the Vikings. From our standpoint of what we consider comfort, the place did not look much, but to the half-drowned sailor sitting before that comforting fire, his eyes still half blinded by the drifting brine from the trough of the sea, this haven then would seem to him a heaven.

We went next to the forts; they were undergoing repairs, but we got a beautiful view of Bergen lying across the water from the battlement on which we stood. Our friend then asked us if we would like to see the spirit shops, as they were considered things of special interest in the town. This traffic it seems is regulated by a kind of local option. By the vote of the authorities only one company is allowed to sell spirituous liquors, and the company is only allowed to take five per cent. of profit, the surplus to be given away in charities. The company have twelve shops in all in this town of fifty thousand inhabitants. The shops are void of any decoration and look as uninviting as possible, fitted with a common deal counter with a row of glasses and a bottle or two on it, and not a chair or seat of any kind to sit down on. You are supplied with one glass of spirits only in one place, and if you want more you must travel on to the next shop. These shops shut up every day during the men's dinner-hour, and at five o'clock on Saturdays.

Restriction exists all over Norway with this effect, that in this country, where drunkenness was one of the prevailing sins, steady industry and sobriety now reign.

In sketching this month's outing I could but give the briefest outlines at the best, the places unnoted that we saw and passed, for number and variety, are of such extent as will fill up the picture for you when you go.

Our journey has been through what is considered the most interesting part of Norway, but only a part. I believe that Christiania and its surroundings can boast more peaceful scenes and fertile plains, or, if more rugged roads are desired, they say that you will find them if you journey on to the North Cape, where from the middle of May till the end of July there is continuous light.

Still, you follow in our track and you cannot help enjoying yourselves, and leave these other parts, as we have done, for future exploration.

We met our American friends here for the last time, and saw them on board their steamer which was bound for Hull, we leaving the same night by *Norge* for Newcastle. We went on board rather early to arrange everything comfortably for ourselves, but when we got on board and looked up the bay from the deck the scene looked charming, with light, colour, and life, and we both exclaimed, "Oh, we must have that!" It was between seven and eight o'clock in the evening, and still the light for such a subject was perfect, but our traps had not come along, so we had either to wait and perhaps lose it, or go back to the hotel and have them brought. So we hurried away and got the party to bring our things at once, and thus managed to get a very good negative before starting.

I could not but heave a sigh of regret as we steamed out of the bay, and I stood upon the deck and watched quaint Bergen receding in the distance, for we had had a very happy time, and one wet day only in the month, and now we were sailing away from that quaint, interesting, wonderful country.

When we got out to sea we found it very calm, for which I was very thankful, for I like the sea best when it's not making much row and noise. but, alas! we sailed right into a bank of fog. We had to slow right on for hours, and perform upon that horn every minute that produces more noise than music.

We had a very pleasant company on board. Our tricycle friends were with us on their return journey also.

We had on board Mr. Howie, who had been photographing Norway with a quarter-plate camera, and a very complete little set he had—everything constructed to take up no space at all; you know the style of things. Some two hundred plates he had exposed; that was what he told me as far as I can remember.

The fog was with us pretty well all the way till we reached the Tyne, when it cleared up. Then Mr. Howie took a picture of the passengers on deck. I don't know how it turned out.

I have sent on a few of the pictures taken from my negatives to the *JOURNAL* office, which may be seen by any interested. They show the class of scenery to be met with in the route we travelled.

Amongst them will be found the pictures taken at Red at midnight, with six minutes' exposure, on a whole plate; lens, Ross 10 x 8 rapid rectilinear; *f*-16 stop. The distance in this picture will be found wonderfully clear considering the time at which it was taken.

And now our journey's over we must part.

"Give me your hand first; fare you well."

MARK OUTE.

Our Editorial Table.

HALF A CENTURY IN MANUFACTURING PHOTOGRAPHIC APPARATUS.

It is always pleasing to have a peep into the interior of a well-established and reputable business, and such a peep is afforded us into the large establishment of the Messrs. E. & H. T. Anthony & Co., of New York, through the mediumship of a little work by Dr. Elliott, one of the editors of the *Photographic Bulletin* issued by this firm.

It is embellished with admirable likenesses of the late Edward Anthony, the founder, and Henry T. Anthony, an original partner in the firm; William H. Badeau, a retired partner, long favourably known in London, where he mostly resided as European buyer for the firm; and of Colonel Wilcox, Richard A. Anthony, and Frederick A. Anthony, its present heads. Much interesting information relative to early photography is given, together with several engravings showing the interior of the workshops in past and present times. "All those now connected with the house," says the author, "are men tried and earnest in their work, men who feel the responsibility of holding untarnished the fair name of the house founded by Edward Anthony."

ONE HUNDRED PHOTOGRAPHIC DODGES; Collected and Arranged by W. INGLIS ROGERS.

THIS tractate contains the above number of "dodges," presumably compiled mainly from hints and formulæ given in the *ALMANACS*, and are in most instances useful. Published by Piper & Carter, price 6d.

WHEELER'S MODERN PHOTOGRAPHIC LABELS.

A COLLECTION of printed labels, gummed and perforated as these are, is always useful, and can never fail of being appreciated by every photographer into whose hands they may be placed. It contains almost everything likely to be used by the modern photographer, printed in bold type, together with some blank labels. Another useful feature is a variety of figure labels for pasting on the corner of lantern slides. Sold by J. T. Chapman, Manchester. Price 6d.

CELLULOID FILMS.

FROM S. Guiterman & Co. we have received a number of celluloid films cut to sizes suitable for coating. Some are "ground" on one side, others being left quite transparent. They are perfectly uniform in translucency, and are admirable specimens of a new preparation of celluloid for photographic purposes.

PATENT COMPLETED.

IMPROVEMENTS IN TELESCOPIIC FRONTS FOR OPTICAL LANTERNS.

No. 7658.—ALFRED WRENCH, 50, Gray's Inn-road, London.—*July 13, 1889.*

My invention relates to telescopic fronts, of the kind described in the specification of former Letters Patent granted to me, dated A.D. 1887, October 31, No. 14,809, for enabling optical lanterns to be used with lenses or objectives of varying focus.

The chief object of my present invention is to provide a telescopic front which is both simpler in construction and cheaper than that described in the specification before referred to, and to this end it comprises the improvements hereinafter described.

In carrying out my invention, I provide a series of two or more tubes adapted to slide one within the other, the inner end of the outer tube being constructed to fit into, or be secured to, the body of the lantern, and the outer end of the inner tube to carry a lens or objective, all in a well-known manner.

The said tubes, instead of being provided with racks and pinions for adjusting them, as described in the specification before mentioned, are adapted to be approximately adjusted by hand, the fine adjustment being effected by means of the lens rack.

To prevent any accidental displacement of the tubes and to ensure their axial alignment when extended, I provide for clamping the end portion of each tube upon the tube sliding within it. For this purpose the outermost end of each tube (with the exception of the inner tube carrying the lens) is screw-threaded externally and made slightly tapering, and upon it is placed an internally screw-threaded collar, or a nut which is correspondingly tapered. The result of this arrangement is that when the collar or nut is tightened upon its thread, it will tend to contract the tube, and so reduce its diameter at the end portion. A number of saw-cuts, or slots, are formed in the said screwed end portion, to enable it to be readily contracted and clamped upon the tube within it.

In order to prevent the tubes from being inadvertently separated, a set screw is advantageously placed in the larger tube, its end extending into slots formed in the tube within it.

I wish it understood that I do not confine myself to the means hereinbefore described for contracting the ends of the tubes, as it is obvious that the same can be considerably modified; for instance, the screw threads on the ends of the tubes and within the collars can be dispensed with, the said collars being fixed by means of bayonet joint, or by means of pins attached to the tubes and working in inclined slots or grooves in the collars, or *vice versa*, that is to say, the pins being attached to the collars and entering slots formed in the tubes.

The claims are:—1. A telescopic front for optical lanterns, the tubes of which are designed to be adjusted without the intervention of racks and pinions, or other mechanism, and which are fixed relatively to each other by clamping the outer end of each tube upon that sliding within it, substantially as described. 2. In a telescopic front for optical lanterns, the employment of an internally tapered collar adapted to be screwed, or otherwise tightened, upon the correspondingly tapered end of such external tube for clamping the same upon the tube sliding within it, substantially as described. 3. The manufacture and use of the improved telescopic front hereinbefore described and illustrated in the accompanying drawing.

THE *employés* of the firm of Messrs. England Bros. had their annual dinner and outing at Virginia Water on Saturday last. Mr. Louis England presided at dinner, and the usual toasts having been proposed, and programme of songs rendered, the company dispersed to enjoy the beautiful scenery in the neighbourhood, meeting again in the evening to return to town in brakes. Altogether a most enjoyable day was spent, especially as the weather proved so fine.

Meetings of Societies.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AUGUST 29.—Mr. J. B. B. Wellington in the chair.

The meeting of this Association was, as had been announced, of a social character, and nothing of a technical nature was brought forward. Views, however, taken by the Chairman during a recent visit to Norway, and by Mr. Medland, taken during a river excursion with the members of the Conference, were passed round, and excited considerable interest. Amongst the Chairman's series, which were all printed in platinum, was a sea scene, including the mid-night sun, taken at the North Cape, and several photographs illustrating the domestic life of the natives of the country.

In reply to some questions, the CHAIRMAN said that the air was generally very clear in Norway, and that mountains could then be seen that were from fifty to one hundred miles away. In consequence of this clearness of the air the eye was deceived as to distances; mountains which appeared to be about two miles away might actually be twenty miles off. In order to secure the white margin to the prints and the proper fitting of cloud negatives when these were used, he temporarily stuck the margin of the print on to the mask with rubber cement.

NORTH MIDDLESEX PHOTOGRAPHIC CLUB.

AUGUST 26.—Mr. Goodhew in the chair.

The CHAIRMAN called upon Mr. E. T. Hiscock to read the following paper on *The Platinotype Process* :—

Although I promised to work the sepia branch of this process, I intend using the black as well as the fabrics. Of the origin and history of platinotype I shall not speak, as we are dealing with the present and the future more than the past; let us then deal with the printing. The paper for use in this process is coated or sensitised with salts of iron and platinum, and is exposed under negatives, exactly as in silver printing, but instead of seeing all detail plainly brought out only a faint image is visible. The sensitised surface before exposure to light is of a lemon-yellow colour. During exposure the parts affected by light become of a pale greyish-brown colour, and, finally, if the negative be quite vigorous, of a dull orange tint under those parts of the negative which present clear glass or nearly so. When the last change has occurred it indicates that the iron salt has been almost completely reduced, and then further action of the light produces no more visible effect on such parts. When printing from a negative having moderately strong contrasts it is frequently found that the deepest shadows of the print are of this orange tint, and are different and lighter in colour than the parts rather less exposed to light. Parts in which this change has taken place are said to be "solarised." Soft-printing negatives, not permitting sufficient action of light in the shadows, do not produce this effect, unless the proofs are over printed. Prints from "hard" negatives are liable to show, when deeply printed, a poorer or more granular black at these parts when developed. Such cases demand a hot and prolonged development. The most suitable kind of negative, when brilliancy is desired, is one intense and full of gradation. Generally a little "solarisation" is desirable in the deepest shadows of the print. The correct exposure (about one-third of that required with silver printing) is ascertained by inspection of the paper in a rather weak white light in the usual manner. A little experience will enable the exposure to be determined very accurately. When examining the prints in the printing frames care should be taken not to expose them unduly to light. The slight action of light not being visible until after development, it follows that the most delicate tones of the finished print are equally visible before development. As to the amount of detail visible, all depends upon the nature of the negative and the eye of the observer. As soon as the exposure of each print is complete it should be placed in a calcium tube or other suitable receptacle containing the dry preparation of chloride of calcium, to preserve it from moisture until it is developed, care being taken to avoid all possibility of contact between the paper and the chloride, which latter would produce white or yellowish-white spots on the print. Having now our prints ready for development, we can start at once. The developer is made by dissolving one hundred and thirty grains of potassic oxalate to each ounce of hot water, so it is left to the operator to make up what quantity he needs. A good plan is to place the prints after removal from the printing frames in a calcium tube with their printed surfaces outwards, and, therefore, convex. In a short time the prints will receive and retain this curvature sufficiently for the developing operation. To develop, take the print in the right hand (its printed surface being downwards), lay the left-hand edge on the developer, and then slowly and continuously lower the right hand until the whole print is floating. The great point is to well preserve and, if possible, increase the curvature of the paper as it nears the liquid. A temperature varying between 150° and 170° Fahr. may be considered the standard temperature for the developer, though higher and lower temperatures may be used on occasion. To test the temperature a chemical thermometer must be used. The print must not be raised for examination during development, nor be taken off the bath too soon, otherwise brilliant and juicy prints will not be produced. The bottom of the developing dish should be covered with the developing solution to the depth of at least one-half of an inch. To clear the developed prints,

these must be washed in three baths of a weak solution of hydrochloric acid. This solution is made by mixing one part of hydrochloric acid with sixty parts of water (for textile fabrics, one part acid and forty-five parts water). The specific gravity of the acid should be not less than 1.16; if lower, more acid should be used. The acid should be colourless. Or citric acid, in the proportion of one ounce to twenty ounces of water may be used. The object of this washing in dilute acid is to remove all traces of iron salts from the paper before it is passed into the plain water. It is obvious that if there be the slightest trace of colour observable in a large bulk of the last acid bath there will be a very appreciable quantity of iron salts present, and, if so, that there must be a proportionate quantity also contained in the body of the print; this plain water will not remove. The use of the washing in plain water is to remove the acid. The prints must not be placed in plain water on leaving the developer because insoluble salts are precipitated thereby on the print. After the prints have passed through the acid baths they should be well washed in two or three changes of water during about a quarter of an hour. They are then finished. Up till the present I have treated only with the black process; with a few exceptions, the sepia is nearly the same. The sepia paper is more easily affected by faint rays of light, and, therefore, increased care must be taken when printing. It does not remain in its best condition for so long a period as the black varieties; there is also a tendency in paper which has been kept to lose some of its warmth of colour. To develop, add to each ounce of the solution of potassic oxalate (one hundred and thirty grains in each ounce) one to two drachms of the special solution supplied for this purpose. The object of the special solution is to give purity to the whites. As regards temperature, over exposure cannot be corrected by a cooler bath, as in the case of black prints. The developing bath, after use, must be kept in the dark. This bath must not be used for black prints. The prints are cleared in a bath of hydrochloric acid (specific gravity, 1.16), one part to sixty parts of water. Porcelain baths or dishes carefully heated are, perhaps, the best to use for a sepia developer. A dish which has been once used in developing sepia prints should on no account be afterwards used in developing black tone prints. In conclusion, I am glad to see the Platinotype Company have dropped the objectionable five-shilling license, that which has deterred many from joining the ranks of platinotype workers; not that the amount was much, but because one's idea was against it. Had it never been charged I believe that bromide papers would not have obtained the same amount of patronage. It is quite palpable to all that platinotype is growing, and is more generally liked both by photographers and the public. One has only to look around the walls of an exhibition to see this fact strongly demonstrated.

The CHAIRMAN then declared the meeting open for discussion or remark. The PRESIDENT (Mr. J. Humphries): If the paper has been kept a considerable time before development it will generally be found that better results may be obtained by using carbonate of soda for developing. Mr. PITHEU remarked that, in his opinion, the sepia was far preferable, as he remarked that prints done by this process strongly resembled a mezzotint. Mr. F. Jones, a member connected with the Platinotype Company, kindly brought four large prints for inspection.

Correspondence.

Correspondents should never write on both sides of the paper.

SIDEREAL PHOTOGRAPHY.

To the Editor.

SIR,—The great distance which separates us from one another entails, as a consequence, that when any article of more than ordinary interest appears in your valuable journal any reply which I might presume to make necessarily arrives so late as to have lost nearly all its interest. Notwithstanding this, however, I venture to request you once more to allow me space in your columns for a few remarks.

In your issue of June 14 last you were good enough to publish some observations of mine upon an hypothesis brought forward by Mr. Traill Taylor in the course of a discussion, the object of which was to account for the formation of discs in sidereal photography.

From the articles of that able astronomer Mr. Piazzzi Smyth, and your contributor Mr. Davis, I gather that the conception, or, at any rate, the adoption, of the hypothesis in question is ascribed to myself. Nothing is further from the truth, for on reverting to my letter—in its excellent translation—I find that I distinctly expressed myself thus: "If Mr. Traill Taylor's hypothesis be correct certain results would follow," &c. I have no wish to claim it as mine; in fact, further on I will give my own opinion about the formation of discs in stellar photographs; but since the supposition that these discs are due to reflection from the second surface of the plate was put forward in the presence of such an astronomical authority as Mr. Common—who to me appeared to concur—I considered the matter worth investigating. What I said was, that if this assumption were admitted as correct it would be necessary to make corrections from the negatives in order to give the true position of each star. This I will proceed to prove.

I have in my possession a number of positives by the Brothers Henry, measuring 24 × 18 centimetres. Their instrument had a focal length of 3.4 metres, and consequently each side of the square, reckoning it only at 18 centimetres, would subtend an angle of 3°. The angular dis-

tance of the edge of the plate, therefore, from the centre of the field would be $1^{\circ} 30'$, and that of the corners nearly 2° . The glass plates upon which the photographs are taken vary in thickness from 2 to 3 millimetres, and their mean index of refraction is 1.5. The image of a luminous point is formed upon the plate by the apex of the cone of rays whose base is the objective itself. Taking only the axis of this cone, forming with the normal an angle of $1^{\circ} 30'$, and admitting the foregoing data as correct, a very simple calculation will show that the distance between the point of incidence of the ray of light and the point of emergence after reflection from the second surface of the plate is 0.1 millimetre.

$$\frac{\sin i}{\sin r} = \text{ind. ref.} = 1.5 = r$$

$$\frac{1}{2} a' = e \tan i'; e = 3^{\text{mm}}; 1 = 1^{\circ} 30'$$

$$\log \sin i' 8.41792 \log t' i' 8.24192$$

$$-\log r 0.17609 \log c 0.47712$$

$$\log \sin i' 8.24183 \log \frac{1}{2} a' 8.71904$$

$$i' 1^{\circ} 0' \frac{1}{2} a a' = 0^{\text{mm}}.05236$$

$$a a = 0^{\text{mm}}.10472$$

Now, according to the scale adopted by the International Congress, 1° is represented by 60 millimetres, consequently 1 millimetre is equal to $1'$ and 0.1 millimetre to $6''$, which amounts to a considerable source of error, seeing that Messrs. Henry and M. Thiele profess to attain a precision of $0.2''$. I am, therefore, right in that *if the hypothesis prove correct it will have to be taken into account in reducing plates*, even though the angles adopted be very small. The reasons which, in my opinion, do not admit of the hypothesis in question being recognised as quite conclusive are, in the first place, the thickness and density of the films at present in use—they are much more opaque than those made with collodion; and also the fact pointed out by Mr. R. N. Lucas, namely, that the diameter of the image of the star produced ought to be the same whatever the magnitude of the star may be. Be this as it may, as soon as the photographic apparatus constructed at Paris in accordance with the Congress regulations is sent here by Professor Cruik, Director of our Observatory, I shall certainly try to ascertain what rôle is played by reflection in the formation of the discs. I am myself inclined to believe that several causes simultaneously concur in producing the effect alluded to, and, according to the extent to which each of these causes asserts itself, widely different results are obtained. Thus all observers do not get discs of the same shape. Messrs. Henry Brothers and Herr von Gothard, for example, have shown perfectly circular and sharply defined ones, while Dr. Lohse, operating with the great Potsdam refractor, obtained discs gradually decreasing in blackness from the centre outwards, so that it was scarcely possible to determine their diameter. The late Warren de la Rue (see Rayet *Notes sur l'Histoire de la Photographie Astronomique*, p. 35) obtained no discs at all, so that he was obliged to place the plate a little out of focus in order to obtain more visible images.

One of the principal causes is, I think, to be found in the movements that variations in (atmospheric) refraction cause the image of a star to perform round its mean position. That such movements do actually take place has been directly demonstrated by the able head of the Cape Observatory with the assistance of his heliometer. "The resulting photographic image," says this authority, "is the integral sum of all the impressions successively produced during the period of exposure." * Another equally important cause—which, however, is well-known already—is the reflection from the "grain" of the sensitive film. This film may be considered as consisting of minute, white, opaque particles immersed in a transparent medium, viz., gelatine. Under these circumstances no more or less hypothetical vibratory action is needed to account for the irradiation; for the ray of light falling on the plate is diffused through the film round the point of incidence, being reflected over and over again by the particles of bromide till it gradually disappears through absorption; and this would readily explain the increase of diameter of the discs according to the position and the magnitude of the star. But the chief reason, as far I can see—and on this point I fully endorse Professor Piazzzi Smyth's opinion—lies in the various errors inherent in the construction of achromatic objectives. In fact, I think it even more difficult to remedy these defects than Professor Piazzzi Smyth stated. For the object

of achromatic photography is to focus on one plane the yellow rays and those next to the line G, which are assumed to be alone capable of photographic action. This may be correct in the case of the collodion processes, which can scarcely be affected by any rays but those of short wave length—called "actinic" in consequence; while it remains almost inert under the action of rays of less refrangibility than the greenish-yellow. Collodion plates, again, can easily be developed by rather intense yellow light. But matters are totally different with regard to gelatino-bromide plates, which, under similar conditions, would certainly get clouded; they are consequently sensitive to the action of rays of low refrangibility, and this sensitiveness becomes still greater when the gelatine bromide is treated with various aniline or other colours in order to obtain what is termed isochromatism or orthochromatism. It is easy to satisfy oneself of this by taking photographs of the solar spectrum upon plates impregnated with colouring matters. The experiments made in this connexion by Professor H. W. Vogel and J. M. Eder are perfectly conclusive. The addition of cyanine, for instance, renders the plate particularly sensitive to the action of the yellow rays, and extends the photographability of the spectrum, even into the red rays, at the expense of the blue and violet; a great many other substances, such as aldehyde-green, picrate of methylo-saline, azaline, chlorophyll, &c., produce similar results.

Now in the orthochromatic arrangements employed in ordinary photography, the only rays brought to a focus on the same plane are those comprised between D and G, and a few more; that is to say, the orange, red, and ultra-violet rays are neglected. In the case of collodion plates this is of small moment, as they are only affected by the rays before mentioned. But in the case of modern plates, especially those that are isochromatic, the rays thus neglected are sure to interfere and produce confused images. The real desideratum, therefore, appears to be an achromatism adjustable according to the maximum sensibility of the plates employed, comprising at least rays of all degrees of refrangibility below B. The requirements of celestial chart-making render the use of isochromatic plates imperative unless all orange, yellow, and red stars are to be systematically left out, and it is much to be desired that the plates which are now being tried by Professor Eder may turn out successful; for with them one may hope to obtain from silver bromide a sensibility uniform for the whole spectrum,* without maxima or minima. With such plates approximate achromatism, such as is now used, will not be sufficient, and they will no doubt compel astronomers to resort to perfectly achromatic reflectors, notwithstanding their defects—defects which Professor Piazzzi Smyth has already pointed out.—I am, yours, &c.,

HENRY MORIZE.

Imperial Observatory, Rio Janeiro, July 26, 1889.

THE PHOTOGRAPHIC CONVENTION.

To the Editor.

SIR,—A letter from Mr. J. F. Peasgood, published in a contemporary of the 30th ult., raises, in my opinion, questions of vital importance respecting the Convention which it would be well to have freely discussed.

I do not propose to say anything on the subject Mr. Peasgood describes as purely a personal matter, except that I cannot see how his Fact No. 2 can be taken to prove the assumption contained in the last line of Fact No. 1.

With reference, however, to the state of the Convention, Mr. Peasgood appears to me to hint that he knows something of the inner working of the Society more than is known to the general body of members, and if this is so I venture to ask him to let his fellow-members have the benefit of his knowledge for the good of the Society; and I would especially ask him—whether the Secretary accepts the challenge or not—"to assign a reason for the present unsatisfactory position," &c. I was one of those members who, at the annual meeting, Mr. Peasgood says "plaintively begged to be told how it is that the Photographic Convention is not a success," and though I do not endorse his description I certainly should have been glad to have had a fuller explanation than was given. As an humble individual member of Convention of very recent date, I should not have thought it seemly to have troubled your readers with any remarks on this subject, but as the representative (at the Convention meeting) of one of the largest societies in the North of England, which Society, I trust, may take an active part in promoting the success of the next annual meeting, I have ventured to address you, in the hope that discussion may arise on the points Mr. Peasgood raises; for if it be true that the Society goes about the country manufacturing enemies, surely it is time that the cause of such a deplorable state of things should be fully set forth in order that suitable remedies may be sought for, and the future position and prosperity of the Photographic Convention established on an enduring foundation.—I am, yours, &c.,

L. E. MORGAN.

Manchester, September 3, 1889.

A CONVENTION FIASCO.

To the Editor.

"I am Sir Oracle," &c.—SHAKESPEARE.

SIR,—The *cacothes scribendi* has once more victimised Mr. Andrew Pringle, and once more after a very short interval has he put his foot into it by writing about a matter concerning which his knowledge was evidently as sadly at fault as in his late silly attempt to depreciate stereoscopic photography.

Smarting apparently under your having shown up a most uncourteous and inexcusable omission in his attempt at summing up the history of photography during the past fifty years, poor, dear "Andrew Pringle, Esq.," has, in some of the other journals, although not in your columns, given a denial to your foot-note statement concerning the rescinding of some decision or other at which the Council had arrived, and by which the Press was to be debarred from publishing any papers until after the Convention was past and had taken its place in history; and this notwithstanding their publication to the world at large by the free distribution of them in printed slip form. Why such a decision had ever been arrived at passes my comprehension, but it would appear that at the eleventh hour—and horrible dictu! in absence of Mr. Pringle—some fragmentary portion of the Council were wise enough to rescind this stupid decision, and, in consequence, two papers in addition to that of the President were published in the pages of your JOURNAL and in those of the *Photographic News*, and this could be got into the one with which he is associated. *Hinc illa lachryme.*

You, Sir, rather quixotically, if you will permit plain speaking, took upon yourself the sole blame of being misled by some section of the Council, declining apparently to put the saddle on the right horse. But it now appears that the publication was authorised by the Secretary of the Convention, and it therefore becomes an official act. Seemingly the President was so much engaged in permitting himself to be interviewed by the *Pall Mall Gazette*, and other papers for what I know, as not to have time to devote to the more important interests of the Convention.

But I started with the intention of saying, and I now say it in a few words, that this attempt to muzzle the Press will, if again made, only serve the purpose of bringing the Convention into disrepute, and, if its heads are well advised, they will never make the attempt again. It is altogether contrary to the spirit of the age.—I am, yours, &c.,

COTTONOPOLIS.

[It certainly would have been better had Mr. Pringle put some restraint on his desire to rush into print until at least he had made himself sure of the ground on which he stood; but there is no accounting for the eccentricities of genius.—ED.]

PHOTOGRAPHERS AT THE BRITISH ASSOCIATION.

To the Editor.

SIR,—Kindly allow me to intimate to any of your readers who may be visiting Newcastle during the coming meeting of the British Association that a large and commodious dark room is at their disposal at the premises named below, and that any information with respect to places of interest in the neighbourhood will be willingly given by—Yours, &c.,

1, New Bridge-street, Newcastle-on-Tyne.

J. ROBERTS.

NATURALISTIC PHOTOGRAPHY.

To the Editor.

SIR,—I fully agree with Mr. H. P. Robinson that no advantage is likely to be gained at present by any verbal argument on Naturalistic Photography. But when it was assumed that all who differed from him had been swallowed up, a word of protest became necessary.

But Mr. Robinson's challenge still remains. He wants to see some photographs executed in accordance with naturalistic principles. Sir, in this *blasé*, withered age such ingenuous inexperience is pleasant to contemplate. Is it Rip van Winkle who speaks, fresh from a ten years' slumber, or is it the voice of the wily controversialist skilled in every move? I will offer him a dilemma in answer: Either Mr. Robinson is asking to see Dr. Emerson's pictures, which he has seen himself any time for the last six years at the *Pall Mall Exhibitions* and in illustrated volumes, or he has been criticising and condemning the work of a photographer without taking the trouble to qualify himself for his self-imposed task by examining the work in question. Dr. Emerson has, as I think, hidden his light away too much in *éditions de luxe*, but nobody is in a position to condemn his theories without having seen his later productions, especially the *East Anglia*.

But granted an open competition between Mr. Robinson and Dr. Emerson, as head of the naturalistic school (though Mr. Davison might run the self-elected champion of the old school hard), Mr. Robinson has left out the essential and vexed point of all exhibitions—the judges. The Naturalisticists do not for a moment look for recognition from any one but artists, and those, as we all know, have long been displaced from the *Pall Mall* juries. To whom does Mr. Robinson so confidently look for suffrages in his favour? Is every visitor to the show qualified, by payment of a shilling at the doors, to have a vote, as for the "Rejected" at Olympia? Photographers have nearly all taken one side or the other by now, and one could tell beforehand which way they would vote. They are perfectly

honest, but they have made up their minds. Even given the pick of eminent artists, are they to be Messrs. Cooper & Herbert, Messrs. Henry Moore & Gow, Messrs. Stanhope Forbes & Adrian Stokes? For my part, I should await with confidence the verdict of the three last-elected A.R.A.'s, though I do not now remember who they are, nor have I here any means of discovering.

But, after all, I shrewdly suspect that Mr. Robinson wants to argue with Dr. Emerson and to exhibit against me. I should not have been worthy to write to you, Sir, if I had not been as fully aware as Mr. Robinson himself that his pictures possess artistic qualities of which mine, as yet, at any rate, have given little sign. But the issue cannot be decided on one narrow vote. Permanence of success, and adoption by the best artists among photographers, can alone settle differences. Is it to be equal focus, dressed-up models, combination printing, and silver printing reluctantly abandoned, or long, patient study out in the country, subordinate detail kept under by every means, study of tone and photogravure, that will win the day?

I have known both the rivals the same number of months, both have been uniformly kind to me. I only hope, in conclusion, that I have said nothing to disturb them in this point of unanimity.—I am, yours, &c.,
Paris, September 1, 1889.

GRAHAM BALFOUR.

PHOTOGRAPHY AT THE DEAL PIER.

To the Editor.

SIR,—Wishing to test the question of extra payment for using a camera on Deal Pier, I took my camera with me one morning last week. I was stopped at once by the man at the gate; he was certainly on the look out for me, as I had a few days before spoken to him on the subject, and had given my intention of trying the question.

The charge made is 10s. 6d. the first day, and 3s. 6d. per day after. On asking why this charge, I was told it was to protect the local photographer. I can hardly see where the protection comes in. I may take Deal when and where I like, in Deal, Deal from under the pier, even the pier itself from Deal, but I may not take a photograph from the pier without a charge of 10s. 6d., in order to protect the interest of the local photographer. I pointed out that no one paid this charge, and that it would rather be to the interest of Deal to invite people there, and to the interest of the pier if a small dark room were placed at the end, and a small charge made to change plates there.

I was told that if I exposed any plates without paying, my double backs would be all opened to daylight. Can they do this?

But perhaps the local photographers there may be able to say something on this matter. Should this meet their eye will they answer?—I am, yours, &c.,

J. W. ZAEHNSDORF.

ON PACKING PLATES.

To the Editor.

SIR,—The last word does not seem to be said on this (for the Lancashire photographer) all-important question.

For those who work in the gallery at home, the ordinary plan of folded paper to prevent the surfaces touching is, in my estimation, all that is needed, that we can hardly expect the manufacturer to consider the landscapeist and to have plates specially packed for him. I have tried many plans for packing plates to be exposed in the field, and my conviction and experience is, that all plans in which the surfaces touch each other, or with intervening paper of any kind touching the surface, result in some failures caused by pressure or friction.

The plan I have settled down to is exceedingly simple and within the reach of all. It consists in attaching to each plate a piece of thick paper on the margin which is covered by the dark slide.

I carry strips of paper of suitable strength, and as I take the plates out of the original box, I set the strips on both sides and press upon the sensitive surface, to which it will adhere firmly. Upon taking out of the slide, the plates require nothing but wrapping in paper, and returning to the original box to be developed at home; this method of attaching paper is easily done by lamplight in any hotel bedroom at night.

I carry these plates in a stock box that will carry from twelve to twenty plates; they lie close together in the smallest possible space, and are easily transposed to a dark slide (single) by feeling in a bag.—I am, yours, &c.,

A. PUMPHREY.

A DAY'S OUTING.

To the Editor.

SIR,—Your correspondent, who so modestly assumes the pseudonym of "Junius," asks what purpose can be served by my communication to your columns of an account of *A Day's Outing with a Camera in Kent*? He also complains that no information is given by me likely "to attract an amateur in search of fresh fields to go over the ground." The elegance of this sentence indicates the literary attainments of the writer; and, I may add, that the idea which possesses him, that my effusion was directed to instruct amateur photographers, exhibits an utter destitution on his part of ordinary perspicacity. The sordid compositional motive attributed to me I put aside with a contemptuous smile, as my only object in recounting a delightful journey with Mr. Clement Vernon, of Maidstone, a master of his glorious art, was to demonstrate that the cultivation of a

poetic love of nature, and a fondness for the music of its engaging symphonies, were not incommensurable but in unison with the exercise of the artistic work of the professional photographer. I can only express the hope that the tympanum of "Junius" may ere long vibrate with these melodies, and that the cultivation of a spirit of Christian charity may lead him to award his fellow-man credit for the same honest motives he may claim for himself.—I am, yours, &c.,
R. W. H.

Exchange Column.

* * No charge is made for inserting *Exchanges of Apparatus in this column*; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Exchange quarter-plate cold press (14×14), camera and lens by Phillistr (landscape, 10×12), for enlarging lantern (in good condition) for quarter-plates.—Address, A. L. SMITH, 233, Uxbridge-road, Shepherd's Bush.

Will exchange fine old mahogany stereoscopic camera, rack-and-pinion movement, two dark slides with carriers, also fitted with mahogany hood and flap shutter, all in splendid condition, for Lancaster's quarter-plate Instantograph set, with extra dark slides (of recent date).—Address, R. S. Coldershaw-road, Ealing Dene.

Answers to Correspondents.

* * Communications relating to Advertisements and general business affairs must be addressed to "H. GREENWOOD & Co.," 2, York-street, Covent Garden, London, W.C.

All matters for the text portion of this JOURNAL, including queries for "Answers" and "Exchanges," must be addressed to "THE EDITOR," 2, York-street, Covent Garden, London, W.C. Inattention to this ensures delay. No notice taken of communications unless name and address of writer are given.

PLATINA.—See article by Mr. Lyonel Clark which appeared a few weeks back. The article, *Portraits by Photography*, by G. L. Hurd, in our last, should have been credited to the *St. Louis Photographer*.

BELGAM.—1. Most certainly the preparation with which the paper was coated was not uranic but uranic nitrate.—2. Mono-carbonates are meant.

MESSRS. TEAN & SON send us a rose-coloured sample, consisting of eight 5×4 sheets, of their ready-sensitised paper. We have no doubt it will do all they claim for it.

A.—If you can manage to wait till the next ALMANAC is issued it is probable you will see something that will meet your case. Experiments are now being made to meet this crying evil.

JOHN PRICE.—Sulpho-pyrogallol is supplied by the Platinotype Company ready prepared, and with full instructions for use. The Company do not publish the formula by which it is compounded.

S. R. B.—The lens will certainly be too slow for instantaneous work. If you wish to work with a single lens you had better obtain one of the modern type with the specially large aperture. Some have an aperture as large as *f*-8.

W. BOUGHTON.—The print demonstrates the possibility of taking portraits by the incandescent lamp. But the arc lamp is most generally employed for such portraits, precautions being taken that none of the glare or direct light falls upon the sitter.

X. Y. Z.—We think the patent is still in force, or at least it was a few months back. This you can ascertain at the Patent Office. The present holders of the patent, if it be in existence, will give you all particulars as to royalty, and also supply all the necessary apparatus and materials.

W. C.—The less any of the photographic chemicals are brought in contact with the skin the better. In developing so small a number of negatives as you have to deal with, we should expect no ill effect if ordinary care be taken in the manipulation. There is no reason why the solution should touch the flesh at all.

VERAX says: "I have a very valuable negative, and I tried to print off it on Pizzighelli platina paper, damped it as per instruction, and it stuck to the negative and caused a yellow stain. Can you say what will get it out, as I am anxious to save it?"—Perhaps some reader who has met with a similar mishap will give the benefit of his experience.

W. SIMS wishes to know how to print in silver on ivory, as the carbon process is too troublesome for him.—There is no successful method of printing in silver, as the ivory becomes stained in the operation. Collodion transfers can be made on ivory, but then the collodion film is not so good for colouring upon as the ivory, and, moreover, might possibly peel off when finished.

ALEX. HUTCHISON writes: "Will you kindly give me the formula for salting paper? I wish to make some prints on a special plain paper, and I cannot find a formula in any of my ALMANACS, as I suppose it is such a rare thing now to prepare paper that it is thought unnecessary to give one."—In reply: Innumerable formulae have been published. Here are three: select that which is most likely to suit.

1. Chloride of ammonium	50 grains.
Gelatine	16 "
Water	10 ounces.
2. Chloride of barium	200 grains.
Gelatine	45 "
Water	30 ounces.
3. Chloride of sodium	60 grains.
Gelatine	30 "
Water	10 ounces.

Boil, strain, and use when cold.

S. PHILLIPS says he has met with an accident to one of his lenses. The camera fell over and one of the glasses is cracked. He asks who is the cheapest man to put in a new glass, as he thinks if he sends the instrument to the maker his charge will be too high, and it is only one glass that requires replacing.—Our correspondent had better send the lens to its maker, who will have the necessary data, and probably will charge no more than another optician who has not. Furthermore, the instrument may then be relied upon as being as good as at first, and by the maker whose name it bears.

J. BURNSIDE inquires: "How would you proceed to put a photograph on to ordinary ceramic ware or china? We practice carbon printing, but what is required is that it should stand 'burning in.' Would it be best transferred on to the biscuit ware, or after the ware is glazed?"—In reply: If instead of carbon a vitrifiable pigment is mixed up with the gelatine, then will the problem be solved for our correspondent, especially if precaution be taken to ensure the gelatine containing the vitreous powder not puckering up when subjected to the heat of the furnace. Our own experience has been mainly with glazed ware.

CASTLE.—1. We have referred to the pages quoted in this year's ALMANAC, and find no mention of either of the formulae. You have evidently made a mistake. However, if a solution is saturated, it is impossible to make it more concentrated. For portability you had better take the materials in a dry state and dissolve them as required.—2. It may be obtained at most photographic warehouses, also at some of the oil shops. It is troublesome to make on a small scale.—3. The cause of the precipitation of the gold is that there was some impurity in the water, or perhaps the solution was put into a dirty bottle.

SILEX writes: "I see by an answer in your last number that only qualified chemists are permitted to sell poisons. Is there any reason why others could not give them away? For example, 'Every purchaser of five shillings-worth of goods to be presented with, say, half an ounce of bichloride of mercury.' There would be no selling.—We quite imagine the law is stringent enough to meet such a case as this. Practically it would amount to selling or vending the poison in contravention of the Act, and would doubtless be treated as such by the Court. You had better not attempt to evade the law in this manner.

J. H. B. writes: "I am anxious to know what are the most expeditious methods of obtaining a photo-relief in wet gelatine and also in dry gelatine, with a difference between highest elevation and lowest depression of about one-one-hundredth of an inch. Can this amount of relief be obtained, in true gradation, in the operation of developing a negative? and what are the conditions favouring it?"—In reply: The conditions which favour obtaining relief in a gelatine negative are, blotting off all surface moisture upon removal from the washing bath and drying before a fire by as great a degree of heat as the film will bear without melting. You may also obtain relief by varnishing the negative with gelatine containing bichromate of potash, and exposing to light through the image, afterwards treating it with water.

S. S. writes: "My enlarging lantern with nine-inch condenser and Ross' symmetrical lens (nine-inch focus), stopped to *f*-11, works fairly well with a blow-through jet for enlarging, but when used for reducing (say half-plates to lantern slides) there is a faint blue circle formed on a screen placed in the position of the sensitive plate, even when the light is carefully adjusted in relation to the condenser. There is a falling off in the light, and consequent unequal development of the lantern slide where the blue shade shows on the screen. Can you tell me the cause, and advise as to the cure?"—In reply: To reduce an image under the conditions mentioned, the lens must of necessity be removed farther from the negative than when enlarging, and in order to get equality of illumination the light must be brought nearer to the condenser. If the optical system will not lend itself to this altered state of matters, insert a sheet of ground glass at a little distance behind the negative.

* * As promised, we give with this number the Group of the Members of the Convention. We will give the key to it next week.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting of this Club, September 11, 1889, will be on *Doctoring Negatives*. Saturday outing at Hampstead. Meet afterwards at the Bull and Bush.

HOLBORN CAMERA CLUB.—Arrangements for September.—6th. Technical paper. 13th. Lantern slide making. 14th. Field day to St. James's Park; meet at the Duke of York's Column at three p.m. 20th. Flash-light photography. 27th. Social meeting and lantern display. 28th. Extra field day.

WORCESTERSHIRE CAMERA CLUB.—The first exhibition of this Club is fixed to take place in March next, in the Museum and Art Gallery, School of Science and Art, Kidderminster. It will remain open from the first to the fifteenth of March. Full particulars may be obtained from the Honorary Secretary, Mr. William Ray, School of Science, Kidderminster.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1532. VOL. XXXVI.—SEPTEMBER 13, 1889.

THE DESTRUCTION OR REMOVAL OF THE PHOTOGRAPHIC IMAGE.

At the present day, when to a very large proportion of photographers the chemistry of their art is a sealed book, many useful dodges and practical expedients are entirely unknown, though well understood and practised by a bygone generation. This is especially the case in connexion with the destruction or removal of the impression formed by the action of light, either before or after development.

It is true that the change from collodion to gelatine as the vehicle for holding the sensitive silver salt wrought a corresponding change in the behaviour of the film when submitted to similar treatment, and, undoubtedly, it must be confessed that the collodion picture offers far greater facilities in this respect than gelatine does. To give only one instance, we may mention the action of persulphate of iron upon a developed but unfixed collodion and gelatine negative, respectively, to which we shall refer presently.

But it is not difficult to find many useful purposes to which the power of destroying the latent image or removing the developed one might be put if it existed in a workable form, as, for example, in restoring to a useful condition plates that have been accidentally exposed to light, in making reversed negatives, or even in rendering reusable a plate that has had a faulty image developed upon it. In an experimental way, especially with collodion, all these objects are readily attained, and in the case of Daguerreotype an impressed image may easily be obliterated and the plate restored to proper condition for exposure by merely submitting it to the action of iodine, bromine, or chlorine.

If a collodion plate, after exposure to light, be subjected to the action of chlorine, bromine, or iodine, or the corresponding hydrogen acids, the image or impression will be entirely destroyed, but the sensitiveness of the plate will at the same time be greatly diminished. Nitric acid, chromic acid, or bichromate of potash, permanganate of potash, and many other oxidising agents, as pointed out some years ago by Captain Abney, possess the same power, and with collodion films we have frequently utilised it in practice with complete success.

In the case of gelatine, however, the physical value of the film more than aught else intervenes to prevent full advantage being taken of this power when applied to *films*, though in connexion with *emulsion* the practice of using bichromate of potash to remove fog has long been a recognised one. It is not to be supposed that we mean that it is impossible to so

treat gelatine plates or films for the removal of fog or even of an image impressed in the camera, because only recently we restored and utilised a number of plates that had been accidentally exposed to light by simply soaking them in a five per cent. solution of potassium bichromate, well washing and re-drying. But for the practical purposes of the average photographer the trouble involved and the risk of slight or even considerable imperfection more than out-balance the advantage.

For making reversed negatives, or, to speak more correctly, for making a negative direct from a negative, or a positive direct in the camera, nothing is easier with a collodion plate, developed with alkaline pyro, hydroquinone, or ferrous oxalate, than to treat it after development, but without fixing, with almost any solvent of metallic silver, by which a transparency in bromide of silver is obtained. This is again submitted to the action of development after a short exposure to light, when, of course, a reverse result to that originally obtained is given. Nitric acid is the reagent usually employed, but a better result in every way is produced by ferric sulphate (persulphate of iron), or the double salt of iron and potassium known as iron alum. It must be observed that a wet or other plate treated by the "acid" mode of development is of no use for this purpose, as the image then consists of silver deposited *on* the film, not reduced from the bromide contained *in* it.

But with gelatine plates this method fails, on account, in the first place, of the solvent action of the acid upon the gelatine. We imagined that by substituting iron alum, which has no such action, but rather a hardening one, the difficulty would be overcome, but, curiously enough, another arises in the deposition in the film in place of the dissolved silver of a yellow basic sulphate of iron, which utterly destroys the result. A method of making reversed negatives on gelatine plates based on the removal of the first image was published by Mr. William Brooks some eight or nine years ago. In this, advantage is taken of the almost entire want of action of the alkaline developer upon iodide of silver. The image first developed is treated with a weak solution of iodine to convert it into iodide of silver; after well washing, the plate is exposed to light and redeveloped, the bromide of silver alone suffering reduction, the iodide being subsequently removed by fixing in hypo or cyanide. But the weak point of this method is that the bath of iodine wholly or partially converts the unreduced bromide of silver into iodide, with the result that the second image is an extremely feeble one.

To render a developed plate reusable—by the way, scarcely

a practical application of the principle, though possible by way of experiment—the image must be reconverted into bromide of silver, instead of being dissolved out. This is easily done with a weak solution of bromine or of hydrobromic acid, followed by copious washing, after which the plate may be re-exposed.

NEGLECTED PROCESSES—"WARNERKE'S NEW PROCESS."

THE process here alluded to—which, by the way, never received any definite or distinctive title—was one introduced and patented by Mr. Leon Warnerke early in the year 1881. At the time of its introduction it created considerable interest in photographic circles, inasmuch as in it was involved a new principle, or perhaps rather a new condition, in gelatine emulsion, which up to that period was unknown. Indeed, we may say that, even at the present time, it is not very well known to many whose experience in photography is but of recent date.

Mr. Warnerke made the important discovery that in a gelatine negative developed with pyrogallie acid the parts which have been acted upon by light are rendered insoluble in warm water, while those portions which have not been acted upon retain their original solubility. In fact, the gelatino-bromide film after exposure and development becomes precisely analogous to bichromatised gelatine—an exposed carbon print for example. The soluble gelatine can be dissolved away, leaving only those portions upon which the light has had no influence. One of the greatest advantages anticipated from this process was that glass in the field would be dispensed with and paper substituted in its stead, while, at the same time, other advantages would accrue. For example, halation would be avoided, and the operator would have more latitude in the exposure, as there would be practically two developments, both of which gave a means of modifying the ultimate result. Also, the negatives when finished could readily be either intensified or reduced to almost any extent.

The process is this:—The gelatino-bromide emulsion is spread upon paper instead of upon glass. The emulsion must contain no alum or analogous material—this is an essential. After exposure in the camera the image is developed with pyrogallie acid in the ordinary manner. It may afterwards be fixed or not, for it makes very little difference in the end. The negative thus far completed is squeezed, face downward, on to a glass plate, either collodionised or not, and then placed in warm water. In a short time the paper comes off, leaving the film adherent to the glass. By the continued action of the warm water the gelatine, which has not been affected by the joint action of light and developer, dissolves away. In the end the image consists of the reduced silver in different thicknesses of gelatine, while the deepest shadows are simply bare glass. The negative can now be intensified to any required extent and by any method, one of the simplest being a solution of permanganate of potash. It will be seen that, as the shadows are free from gelatine, there is nothing to be stained. If the image, instead of requiring intensification, is too dense, it may be reduced by using hotter water, precisely as in developing an over-exposed carbon print.

The negative thus obtained is reversed, and in that state is well adapted for collotype, or other processes requiring a re-

versed image. If it be required for silver printing, the negative can be developed on a flexible support and then transferred to a glass plate, or the negative can be stripped from the glass upon which it received the second development on to a gelatine film.

At first sight some might imagine that this process is somewhat analogous to the Eastman stripping process, but a little consideration will show that it is widely different. In the latter process the paper supporting the sensitive film is first coated with a layer of soluble gelatine, upon which the bromide emulsion is spread; this emulsion contains sufficient chrome or other alum to render it absolutely insoluble. In transferring an Eastman negative, it is not part of the emulsion itself which is dissolved by the hot water, but the soluble layer upon which it is supported. In the finished Eastman negative there is precisely the same amount of gelatine in the deepest shadows as there is in the highest lights; consequently, these negatives are not amenable to the same method of intensification as are the Warnerke ones—the permanganate of potash, or any of the dyes, for example.

One of the numerous applications of the Warnerke process, mentioned at the time of its introduction, is the production of carbon enlargements direct from the original, thus dispensing with both the transparency and the enlarged negative. In this case the pigment is added to the bromide emulsion, so that a "carbon tissue" is obtained, combined with the sensitiveness of bromide paper. The enlargement is made as with ordinary bromide paper, except that the image must be developed with pyrogallie acid; then it is squeezed on to transfer paper, and developed with hot water as a carbon picture; thus an enlargement in pigment and silver is obtained, but the silver can afterwards be removed, if thought desirable.

Mr. Warnerke's process is a thoroughly practical one, and at the time of its introduction we produced a number of excellent negatives by its aid, and which had all the qualities its originator claimed they should possess. The process, however, has not come into general use. Photographers, it is well known, do not, as a rule, care very much for extra trouble, notwithstanding that it might lead to better results. This process certainly does entail more trouble, and also requires more skill in its working than other processes by which very similar ends may be attained. First, a good negative has to be obtained, and when this is secured the experience of one familiar with the details of carbon printing is required for the second development and following operations. It will be very manifest that however good a negative might be in the first instance, it could be utterly ruined in the second operation, or in the later ones of transferring the film.

EVERY one knows the difficulty of filtering large quantities of material when the object is either to preserve a precipitate or classify a fluid. For example, a few pounds of chloride of silver cannot be freed from the major portion of the water accompanying it in residue collecting without a considerable expenditure of time, and the same difficulty is felt in purely experimental work with silver precipitates. Innumerable plans of folding the filter paper, or making the funnels with deep plates have been devised, the best for rapid filtration, perhaps, being the plaited filter. From Mr. Edison's laboratory comes another method still, the inventor being Mr. R. A. Fessenden, chemist at that eminent electrician's laboratory. Perhaps the simplest plan of describing it is to say that the filter is folded into the well-known form that schoolboys fold a small piece of copy-book to attach to the end of a splinter of wood to form a dart. A filter so folded is

clipped between opposite folds by a piece of glass rod bent almost double, and then placed in the funnel; by this means, the whole surface of the paper is exposed to the liquid instead of, as usual, one-half only; and, further, there is no impediment to the flow of the filtrate by a threefold thickness of paper for one-half of the exposed surface. The new method promises to be really useful.

It is a subject for surprise that, beyond coating rollers or plates with nickel or silver, no advance has been made in the direction of preserving from rust that necessary instrument for photographic finishing—the rolling press. Yet so liable is the polished roller, or the steel plate, to become entirely spoiled by the action of damp air, that it might be thought the inventive power of the producers would be brought to bear upon it. We cannot but think, and manufacturers may take the hint, that the Bower-Barff, or some cognate process, might with advantage be utilised to this end. Those methods of treatment cause the absorption of oxygen in such a form that it no longer attacks the metal under ordinary atmospheric conditions, and bright surfaces of iron and steel can, after being treated in the suitable manner, be exposed to air and rain without tarnishing or rusting.

THE present year has been marked by no great periods of continued excess of atmospheric moisture, like some of its predecessors, yet, for some unexplained cause, we have had brought before us a large number of cases in which mildew, which does not come in dry places, had attacked photographs—chiefly carbon prints worked up both in Indian ink and black chalk. Whether caused by the mode of treatment the artist had given them, or through the inherent qualities of the gelatine itself, we need not now stay to inquire; we would merely mention the expedient adopted by one of our readers to prevent such unfortunate *contretemps* occurring. He makes a point with every picture he puts in a frame to place at its back, and seal up with the pasted backboard, a few drops of carbolic acid. This being a great germicide, he believes that it would destroy all mildew spores that might gain entrance and otherwise grow and fruit and multiply—mildew being a low order of plant life which, when it comes to maturity, has a distinct fruiting period.

A PAPER on *Telescopes for Stellar Photography*, by Sir Howard Grubb, F.R.S., read before the Society of Arts, is now published. All who take an interest in astronomical photography will be interested by its perusal, and gain a much more intelligent knowledge of what photographing the stars really means than by any other single paper published. A most interesting description is given of the principles and method of star mapping as applied by the Congress of Astronomers at Paris last year—lenses, cameras, and the necessary clocks for driving, all coming in for a due share of attention and lucid description.

SIR HOWARD states that the instrument made for Mr. Isaac Roberts, of Liverpool, by which, in the "exceptionally wretched atmosphere of Liverpool," he obtained those remarkable photographs which attracted lately so much attention, is the first example, as far as he knows, of an instrument in which a successful attempt has been made to drive for any considerable time without eye and hand guiding. This is a vast improvement. "No one," says this expert, "who has not tried it can imagine the strain required to keep a constant watch on a star image for thirty or forty minutes, but if attention be only required for a second or so every few minutes, there is no difficulty or irksomeness whatever."

We may explain that if a fixed telescope were used for any star, the rotation of the earth would carry the star quickly across the field of view and out of sight. The astronomical clock obviates this by causing the whole telescope to turn so as just to counteract the disappearing tendency, with the result that the star keeps always in the centre of the field, or about that. "About it" is, perhaps, the most correct term to use, seeing that the image may move, and does move usually, out of the centre. The remedy is by means of another

telescope to keep the star really exactly in the centre, and when it appears inclined to deviate, to keep it rigidly in position by means of a hand attachment acting supplementally to the driving clock. And a very tiring task this is, as we just quoted; an instrument capable of acting so as to obviate all deviation except for a brief interval will be more than a boon; it will materially facilitate the progress of stellar photography. Let our readers imagine, if they can, the labour and pain involved in taking the great Nebula-in-Orion photograph, which required an exposure of about four hours, but which in the lecture is described as "an example of celestial photography never yet surpassed."

SIR HOWARD GRUBB refers to an article he wrote in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1869, in which he gave a sort of prophecy which has been fulfilled. He wrote then that "for the development of celestial photography we should have to look to the chemist, not to the optician—in other words, that until we obtained more sensitive plates we could not expect much advance." How true! and what advance has been made since the advent of such plates!

ECHOES.

THE "Jubilee" Convention is past and gone, and proved, as it was expected to be, a "big success," both as regards interest and attendance. But somehow or other it seems to have left a trail of dissatisfaction behind it. The editor of one of your contemporaries complains that he had to "pay to go in," so next year I expect the Local Committee at Chester will be wise enough to provide him with free quarters at the Grosvenor Hotel, place a carriage and pair, or a special saloon carriage, at his disposal for the excursions, together with a complimentary member's "pass." Such generous supporters of photography deserve encouragement.

Another contemporary editor finishes up a couple of columns of misstatement by asking the question, "Is this journalism?" I am sure I can't say with certainty, because journalism has its phases and freaks. But it is certainly a new feature in photographic journalism to attempt to make capital by a venomous attack on a rival editor, based upon an untruth which is almost deliberate from the carelessness of facts displayed. It must be consoling to the feelings of the editor of this journal, the one attacked, to know that his contemporary is at home in that spot in the Midlands to which the perpetrators of "shady" acts are usually relegated.

My own only complaint against the Convention is in connexion with the Exhibition, but I dare say I may be wrong in my view. That is, that the Exhibition, in London at any rate, was unnecessary and a mistake. In a provincial town the collection together of the latest novelties in pictures and apparatus may prove an interesting attraction to non-photographic visitors, and even to some of the country members. But in London these latter will naturally gravitate to the headquarters of the principal dealers and picture makers, where they can see more than it is possible to condense into an Exhibition. In fact, the case was very admirably summed up by a "lay" acquaintance of my own, who had devoted an evening to the Convention: "I didn't think much of it; I have seen better in the windows in Regent-street."

From the London Convention to the Paris Congress is but a step, but so far as I can judge from the meagre accounts supplied, the latter appears to have been as much a failure as the Convention was a success. I fully agree with the spirit of the leading article in the JOURNAL, but it is a pity it subjected poor Professor Stebbing, in his capacity of your correspondent, to the indignity of having to take a "back seat" at the dinner, to which he was honoured, along with M. Warnerke, with a "free ticket." But I cannot coincide with him in thinking that the lavish expenditure of two free dinner tickets entitles the French authorities to be considered as having dealt handsomely with foreign representatives. The remission of 20 francs entrance-fees to two self-styled delegates is, too, rather a symptom of credulity than of special welcome to England.

After all, what has been the result? Practically nothing. The Congress has endorsed the British standards for screw flanges, has

proposed a new one for diaphragms, and suggested a scheme for using the acetate of amyl lamp as a standard of light. But this last really desirable question is left in a delightfully uncertain state for anybody else to work out to a practical issue, for it is very certain that the next year's Congress will prove flatter than this. The most comical part of the light-standard question is, however, that, out of compliment to M. Warnerke, the Council mention his standard sensitizer in order to say that they do not recommend it!

Reverting to the subject of caustic alkalies, it has suggested itself to me that in following the instructions and figures given in the leading article a week or two since, the photographer may be placed in a position of the greatest uncertainty on account of the unreliability of the carbonates obtainable. Washing soda, or crystallised carbonate, for instance, is sold of very varying composition, containing from two to ten equivalents of water of crystallisation, and these crystals are, moreover, subject to efflorescence. Carbonate of potash, on the other hand, is so very deliquescent, that it is almost impossible to keep it in the anhydrous state: consequently, the poor photographer will find himself little better off if he trusts to the commercial supply of carbonates. It may be useful, then, to remind your readers of a ready means by which pure anhydrous carbonate of soda or potash may be obtained anywhere where a pharmaceutical chemist exists. This consists in taking the corresponding bicarbonate as the basis to work upon, and driving off the loose atom of carbonic acid by heat. This can be done by exposing on a plate in a hot oven for an hour or so, or by "roasting" on a clean fire-shovel over a clear fire, or boiling the solution for some minutes. Or the bicarbonate may be treated directly with calcium hydrate, proper allowance being, of course, made for its difference of atomic weight; that is to say, for the proportion of real alkali it contains.

JUNUS.

ROYAL CORNWALL POLYTECHNIC EXHIBITION AWARDS.

PHOTOGRAPHIC DEPARTMENT.

Professional Section.—First silver medal: W. J. Byrne, F. W. Edwards.—Second silver medal: W. W. Winter, H. P. Robinson.—Special first bronze medal: R. W. Robinson.—First bronze medal R. Keene, T. Protheroe.—Highly commended: Mrs. Chenalls & Sons.

Amateur Section.—First bronze medal: A. K. Barnett, Henry Littler, F. C. Cembrano, M. E. Austin.—Second bronze medal: A. R. Dresser, Rev. H. B. Hare.—Highly commended: E. Brightman, Miss E. L. Hare, A. Stieglitz.

Photographic Appliances.—Second silver medal: F. W. Hart.—Highly commended: Catheart & Peto.

Full report in next issue.

THE PHOTO-MECHANICAL PRINTING METHODS AS EMPLOYED IN THE JUBILEE YEAR OF PHOTOGRAPHY.*

RECENT METHODS OF MAKING TYPE BLOCKS FROM HALF-TONE SUBJECTS.

ANY impression in a fatty ink, of the nature of printers' ink, which may be transferred to stone or zinc for printing after the lithographic method, may be considered as the germ of a typographic printing block, as, if such an impression is transferred to a zinc plate, the uncovered parts may be etched away so as to leave the covered parts standing in high relief. The details of the method of thus etching a zinc plate have already been given. Let us take the reverse case. One has a typographic block, and it is more convenient to print impressions by the lithographic machine than from the block; it is only necessary to make a print from the block and transfer it to the stone. Thus it will be seen that lithographic printing and typographic printing are very closely connected, so closely that when a subject is prepared for one it may be printed by either, as convenience may indicate. The *Official Gazette* of the American Patent Office is set up in type, but the printing of all, excepting the index sheets and the covers, is done on a litho machine.

These remarks bring us to the point where photo-lithography and photo-typography may be considered together, and that the making

of a fatty transfer is equivalent to the production of a printing surface suitable for printing by either method.

In making a type block from a graduated photograph, the first step is to translate the evenly graduated tints of the latter into a line system, or a stipple of corresponding intensities. When a photograph is transferred to a wood block, this is done by the personal skill of the individual who engraves the block; but this is by no means to be regarded as photo-engraving proper, so my remarks will be confined to processes in which the translation is effected automatically.

There are many methods of so translating the tints into points, lines, or dots, that even to mention all would be impracticable.

In an earlier part of this paper, the method of Asser was referred to, a photo-lithographic transfer being made on a sheet of starched or pasted paper, made sensitive by means of potassium bichromate; and by putting down such a transfer on zinc, and etching into relief, excellent results may be obtained. It may also be mentioned that, as long ago as 1866, Messrs E. & J. Bullock, of Leamington, obtained a patent for a mode of photo-lithography in half-tone, and a print issued during the year in question with *THE BRITISH JOURNAL OF PHOTOGRAPHY* shows that their work was equal to anything that has been done since. Why, then, you may ask, did not the process become a great thing commercially, and make its mark? The answer is simply this—the invention came before its time, neither good lithomachining nor zinc-etching being practised at the time. The expired patent of Bullock Brothers, (No 2954, 1866) will be read with interest, and its value is well illustrated by the fact that the essential points of it have been claimed by very many subsequent patentees. Bullocks claim the production of reticulated transparencies; by copying a negative over which a grained surface is laid this transparency affords the means of making a grained negative: but the method by which their best work was made is a second process included in the same patent. Ordinary or photographic paper is coated with a glutinous substance, and printed with a reticulated pattern. Let me now quote from the specification:—"In this case the specks of ink themselves form a medium, and by their aid excessive contrasts are avoided, and half-tones secured. Such a picture, when so obtained, is passed to a lithographic stone or zinc plate, and a printed proof produced therefrom; by the aid of chromo-lithography coloured proofs may be produced." The coating of the paper with a glutinous substance may "be conducted in connexion with bichromate of potash or bichromate of ammonia." The said transfer paper may be used, "whether the impression be a lithograph, a zincograph, an impression from an electrotype, or from an engraved or etched plate."

By transferring a coarsely grained collotype to stone or zinc, a very good grain image is obtained, and the coarse reticulation of the gelatine is very much facilitated by adding chloride of calcium to the sensitive mixture. The following answers very well:—

Gelatine.....	6 parts.
Water.....	60 "
Bichromate of ammonia.....	1 part.
Chloride of calcium.....	2 parts.

Printing surfaces thus obtained, whether lithographic or typographic, resemble those of Pretsch or of Dallas on the one hand, and those of Sprague on the other hand.

In order to obtain a transparency in which the tints are translated into points, lines, or dots, Algeyer and Bolhoevenner have recently suggested a method in which a collotype plate is exposed under a negative; and after this plate has been soaked and inked up in the usual way, the fatty image is reinforced by dusting with an opaque powder. This method is of course dependent on the reticulation of the gelatine for the production of a grain. From such a transparency a negative may be made by contact printing, and from this a photo-litho transfer by any one of the well-known methods.

Meisenbach, of Munich, has recently obtained a patent in which he claims some details as to well-known methods of breaking up the grain of a photograph by means of a network, and he more especially claims the shifting of the network during the time of exposure. As regards this point, something similar was described by Bertschold in the volume of the *Photographic News* for 1859. Notwithstanding the fact that one cannot find any very striking features in the patent of Mr. Meisenbach, this gentleman has produced some typographic blocks of surprising excellence, examples of which are now before you.

We now come to an important feature in connexion with the subject, that is to say, the direct translation, by mechanical means, of the gradations of depth existing in the Woodbury relief into corresponding shades of stipple or granulation; but before entering into these, let me call your attention to a method of granulating the relief itself, which Mr. Woodbury has made the basis of a method by which excellent printing blocks have been made.

* Concluded from page 590.

Mr. Woodbury exposes his ordinary relief tissue under a transparency with a piece of network interposed, the effect of this being to produce a decided grain all over the high portions of the resulting relief and no grain over the deep parts, intermediate portions being grained to an intermediate extent. A reverse cast from the grained relief thus obtained is the printing block. This mode of procedure is subject to one disadvantage in actual practice, as the various printing parts of the resulting block do not lie accurately on one plane, as is the case with a block made by etching a plate of zinc into relief. Mr. Woodbury, however, overcame this objection by a modification of the process in which a transfer is obtained directly from the relief.

The following quotation from Woodbury's specification of 1873 will serve to fully elucidate the nature of the process referred to:—"I prepare sheets of bichromatised gelatine, such as is used in the process called 'Woodburytype,' and expose these under a photographic positive to the action of light, but interposing between the positive and the gelatine film a transparency on collodion or mica of what is known as mosquito netting, Brussels net, tulle, and so forth, which has the effect of breaking up the resulting relief into a multitude of fine square hexagonal lines; or for some subjects I interpose a transparency on mica or collodion of any design of a similar nature that will have the same effect, such as an impression from a grained stone, or the same from a number of fine ruled lines. The sheet of gelatine, when washed, will give a relief having the positive photograph represented by a number of lines, instead of the simple half-tone it originally possessed. I then take an impression from this by means of hydraulic or other pressure in any soft metal, and use the block so obtained for printing at a type press when only a few copies are wanted; but when large numbers are required, I electrotype the same in the ordinary way. I prefer to use diffused daylight or sunshine through ground glass or tissue paper to produce the relief, as in that case the light in the parts that represent the white creeps round the lines, thus partially obliterating them in that part, and leaving them strongest only in the parts printing dark. I sometimes adopt another method. I take a negative of the network by transmitted light, and copy this together with the negative to be reproduced, thus producing a positive with the lines already thereon, from which I proceed to make a relief and blocks as stated."

Mr. Fred. E. Ives, of Philadelphia, published, in 1878, a method of translating the smooth photo-relief into stipple, and this method may be regarded as a new departure. According to the method of Ives, as described by him in 1878, and patented in the United States, the essential features of his method consist in inking the Woodbury relief, and pressing against paper which has been grained or embossed, somewhat after the fashion of bookbinders' cloth. Under these circumstances the projections on the paper become completely crushed down by the inked relief where the gelatine is thickest, and a solid black results, while the more shallow parts of the relief only tip the projection on the paper with ink. Intermediate thicknesses of relief produced a medium effect. You will now please note the effect of pressing this sheet of grained paper against the inked Woodbury relief, a picture in black and white resulting, the shades of the original being represented by the varying extent of the closely packed dots which constitute the picture. The translation into stipple thus obtained may be used as a transfer for putting down on stone or zinc, but if preferred it may be re-photographed. Ives also made printing blocks by casting from the grained surface which had been compressed by the gelatine relief, although these were not found to be quite equal in quality with those obtained by the first-mentioned method. A subsequent modification of Mr. Ives's method gives results much more easily and economically, as he has succeeded in substituting a "swelled gelatine" relief for the more expensively produced Woodbury relief. In a letter to me, Mr. Ives says:—"The relief which I now employ is a plaster cast from swelled gelatine, which is secured so easily that an apprentice, seventeen years of age, makes them acceptably for Crosscup and West. On the relief the lines and stipple are impressed by means of a printing film of elastic, V-shaped, stippled lines, in a manner which gives the operator considerable control of the effect. The line and stipple picture on the plaster relief is then stripped off for lithographic transfer or etching, by a method so simple and perfect that it astonishes all who see it done. Formerly, I had to reproduce the impression by photography in the camera, and by this operation could not avoid losing much of the delicacy of the original, which is wonderfully delicate, sharp, and clear in line. I have to secure ruled plates for moulding closer lined printing films before I can apply the transfer method of reproduction for fine work; so it may be months before I shall show you what fine results I can secure in this way."

The following reprint of Ives's original declaration will be of interest:—"Ithaca, New York, August 12, 1878. I, the undersigned,

have to-day invented a method of obtaining relief plates for the typographic printing press from ordinary photographic negatives, which may be described as follows:—1st, From an ordinary photographic negative, a relief in gelatine, similar to that used in the Woodbury-type process, but perhaps in lower relief, is obtained. 2nd, This relief is carefully and uniformly inked with fine printers' ink, and pressed between two flat surfaces (or between rollers) against paper or other material, upon which is stamped or otherwise produced a fine grain or other suitable surface. The inked relief being highest in the black parts, presses down the grain of the paper on the corresponding parts, and the removal of the ink by the paper from those parts of the relief produces a black impression, while upon those parts where the relief of the gelatine is lower, the grained surface is pressed less, and the ink taken up in spots, the size of which depends upon the grain of the paper, and the amount of pressure, and producing an effect similar to that of crayon sketches made upon such a surface. 3rd, Relief plates may be made from this impression, either by the usual photo-typographic processes, or, perhaps, by obtaining a cast or electrotype of the impressed surface of the paper or other material used to receive the impression from the gelatine relief.—FRED. E. IVES."

The broad principle of the Ives method, which consists in pressure of the relief against a grained or stippled surface, has been the subject of several subsequent patents and inventions. We find that, in 1879, Petit, of Paris, took out an English patent for a method nearly identical with that of Ives, and soon after another patent by Dredge followed; this latter, however, indicating novel methods of working. A process of quite a similar character is the "Crayontype" of Ad. T. Eggis, which was published more recently. Mr. Eggis, instead of inking the relief, takes an inked film, such as manifold copying paper, and lays this on the relief. The grained paper is now placed over and pressure is applied. If the grained paper sold for producing crayon effects in lithography is used, very excellent transfers are obtained.

Mr. Eggis, writing in the *Photographic News*, thus describes the method:—"This process gives results good enough to have allowed the taking of a patent, but I find it preferable to describe it for the public benefit. I call it crayontype, for the images it produces are much like those obtained by the artist with a lead pencil (crayon in French). This is how I proceed:—I procure or produce, to begin with, a gelatine positive on best plate glass (*glace*), obtained by the known ways, in relief. The highest point when dry should not have more than one millimetre. The other necessary implements are, first, grained (or lined) paper, of same kind as is used by the artists for their drawings destined to be etched; second, a few sheets of blue or black transferring paper (*papier à calquer*, thin paper coated with a greasy substance and coloured); third, a small press. Having these at hand, I take the gelatine positive, lay it on the stone or metal table of the press; on the relieve I place a sheet of transferring paper, the prepared face turned upwards. On this I lay the stippled or grained autographic paper, face downwards, touching the greased sheet. Over all this I place a fine polished steel sheet, well planed. I put the whole under the press, and slowly pull down the lever in such a manner as to give a smooth and graduated impression. Afterwards separating the whole, I find on the grained paper a good and often a perfect stippled reproduction of the gelatine relief. This reproduction being formed by a greasy substance, I am able to transfer it at once directly on stone for lithographic purposes, or on metal to be etched in the usual manner. The production of such an image will be easily understood; it is much the same as the direct drawing with a pencil on the paper. Instead of the artist pressing more or less his graphite on the paper, the gelatine relief (which corresponds more or less to the lights or shadows of the photograph) presses more or less on the paper, and gives the true gradation of the original. The work of the hand is mechanically imitated very closely indeed. The crayontypes present a different grain, which may be chosen according to the work to be done. It is at least more artistic than the usual regular stippling."

Other modes of effecting the translation of the relief by pressure on grained surfaces have been patented by Mr. Zuccato.

The first method consists in first planing a piece of type metal or similar surface in a series of ridges, or a series of pyramids, as the case may be. The plate is then inked, and instead of pressing the relief directly on the inked plate, a piece of very thin paper is interposed; the relief crushes down the pyramids in proportion to its depth. The pyramid of type metal is spread out, and forms a sharply cut outline on the paper, and in this way a transfer is obtained which has a remarkable clearness of outline, almost like the cleanest cuts of the graver.

It will illustrate the matter better if, instead of inking the plate first, the relief is pressed directly against it, and you will then be able to see the flattening of the lines or pyramids.

Two other modes of working have also been patented by Mr. Zuccato. In one he interposes between the relief and a sheet of transfer paper a piece of gauze, or a piece of silk which has been inked with transfer ink. Of course, what then takes place is similar to what happens in the case of the plate; the threads of the gauze get crushed out to a greater or less extent, and form lines of greater or less width, but this method in which the gauze is crushed down is not nearly so perfect as the method with the plate of type metal.

The Woodburytype process and the Collotype process, not having undergone any very remarkable developments of late, and being generally known as regards their main features, do not need special consideration in relation to our present subject. THOMAS BOLAS.

COLOURED PHOTOGRAPHS.

VI.

WE have now come to a point when a very serious matter has to be considered—the choice of materials. There is nothing more essential to an artist's securing comfort in his work and completeness in his effects than the quality and appropriateness of his materials. On this point let us banish all considerations as to price; the one and only consideration should be that they be good—the best, in fact, procurable. Take my word for it, they will, if really good, very soon and effectually reimburse you for your extra outlay. In my own case, I find it pays me, in saving of time, to use a good brush for work that may to many appear workable with second-rate ones. But, as I say, my time is saved, and to such an extent that the difference in cost of the good and the middling brush is a matter worse than foolish to hold in serious consideration.

In starting on the subject of materials, especially when in connexion with photography, I think it only fair to place in the foremost rank Mr. James Newman. His colours are undoubtedly good, but it is not altogether on this score that I mention his name here. It is because he has devoted years of study in producing various specialities that may help the artist in his task of colouring photographs.

One of his specialities is his "sizing preparation," which will be found a great help in more ways than one. All who have attempted to colour photographs must have noticed how awkward the various surfaces appeared to be, and how difficult it was to get the colours to work nicely upon them. This difficulty is overcome by the use of the above or Newman's "prepared size." The latter is very strong, and should be diluted with water before using—three parts water to one of size is a safe proportion. Change of climate will not affect this preparation. On some photographs it is difficult, if not almost impossible, to get a wash of colour to float evenly over their surfaces. This may be the result of the natural quality of the photograph, or be owing to the fact of the surface being rubbed in some way. To smooth this difficulty we cannot do much better than use the "sizing preparation" mentioned. A little of this "size" may also be used with the colours to some advantage, as it produces in them a tendency to become fixed, and so allow of their being worked over without much risk of disturbing them. I need scarcely say that I am treating water-colour painting for the moment; oils will come later. Washed over carbon prints, it greatly enhances their appearance as well as fits them for the application of colour, but does not impart a gloss all the same. This latter is a very considerable advantage. Thus we have prepared our photograph, and, assuming for the moment that we have coloured it, we can now use Newman's "Diamond" enamel paste, which imparts not only a beautiful finish (to either plain or coloured work), but also a depth and brilliancy combined with a certain degree of protection from the evil influences of exposure to the atmosphere. There are many cases where a bright surface would be a disadvantage, and in such it should not be used; but where suitable, it will not only produce a bright surface, but it will also hide all offensive touchings or markings which might be too prominently observable without its application.

Brushes! Ah! how troubled are we at times to get good ones! Every working artist should keep a goodly supply in reserve, and they should be the best. He must have some fine-pointed *sables* for stippling and working out the finer details, and larger ones for laying in the washes and broader portions of his picture. There is no absolute rule which can be laid down for the selection of brushes. For fine work do not get the brushes too small; see that the point is fine, but let the sables themselves be of moderate size. If anything, incline to the larger than to the smaller sizes. A good brush should spring well when pressed with the finger, and always preserve a good point. Tastes vary as to use of brushes, and I think I am safe in saying that every one should select those which afford the maximum of comfort

in working, but they should *always* be the best in quality. It is altogether a matter of taste, too, whether they are mounted in quill or metal. Personally, I use the latter, as they stand the wear and tear better. This may be considered as the *economy* of art. As I have said, a *fine-pointed* brush should be used for stippling; for hatching, such is not necessary, in fact, it may be considered rather a disadvantage. A red sable brush that has been in use some time, and which has the point well worn off is best adapted for this method of working. It is best to hold it as far as is conveniently possible from the point, between first finger and thumb, with the middle finger under it as a kind of extra steadier. It must be worked, too, in such a manner as to allow of the free movement of the wrist and arm. It should be our constant endeavour to acquire a firm touch with the brush, and not work too much upon the point of it.

For many years past (too many to insert here) I have been in the habit of using Winsor and Newton's brushes, and have invariably found them reliable and good. They are not cheap, nor do they profess to be as regards price, but they always try to supply the best article. I have always held that a really good article is worth a fair price, and I feel sure all sensible men will think the same if they give the matter due consideration. I have known them rise their prices at times considerably, and when I inquired why they did so, they very kindly explained that it was owing to the difficulty in procuring the sable with sufficient *spring* that necessitated their charging more for the production of a first-class brush. One should not murmur at the price varying a little, provided there be rational cause, but it would be quite another thing if the *quality* varied. This, I must say, in common fairness, I have never found; their brushes are always well selected (this is most observable when sables run bad), and if they sell you a set of brushes and say they are first class, you can confidently rely on them. At least, such has always been my experience.

I do not wish to infer by this that good brushes are produced by this firm alone, or that a *cheap brush* by some other maker may not be a good one, but I do say that such brushes as the latter are not, as a rule, dependable.

We should be provided with a china palette, a nest of saucers, and one or two slanting tiles. When we wish to apply large washes it would be impossible to have sufficient colour mixed upon a palette, and, in such instances, the saucers or slanting tiles will prove our friends. India-rubber, ink eraser, sharp knife, scraper (procurable at any artists' colour shop), should also form part of our kit. Some painters use a lancet, while others use a needle. Poor artists in the dull season generally have the latter. It is very unpleasant. I have experienced it, and know.

Some very finely powdered pumice stone, a bottle of gum-arabic water, not too thin, as by dilution with little water it can easily be reduced, an agate burnisher, and a few drawing pins, may be said to almost complete our list of wants other than our colours. If engaged on large work or oils I would recommend the use of a *mahlstick*, as it gives considerable freedom to the hand in working.

If any considerable portion of your work comes under the heading *large*, an easel will be necessary, and for general work and usefulness a "Corbould" is undoubtedly the most desirable. Any easel, however, if sufficiently firm, will answer our purpose quite well enough. For the smaller work an easel will not be indispensable, and may be found even awkward. If, however, we have one, by all means let us use it. One soon gets use to it, and I know many who prefer its use even for the smallest work. When thus used we will have to include a drawing board, to which—mounted on the easel—we pin our work and go ahead. I think a desk suitably placed upon a table will be found more convenient, notwithstanding, for the very small work.

I may here mention that a small pot of prepared *ox-gall* will be found very useful at times. For working on ivory it will not be required, but for albumenised paper, which at times appears very greasy as it were, it will prove of great assistance and be almost indispensable. The less used, however, the better, as too much will have a ruinous effect upon the paper or photograph, and in some cases destroy the delicacy of a transparent tint. All cases in which ox-gall appears necessary, it should be washed over the entire surface of the picture, in weak solution, with a camel's-hair pencil. Camel's-hair pencils are not practically useful for painting generally, and this is owing to their not having sufficient *spring* to give a reliable touch.

Some prefer red sables to any others on account of their greater stiffness, although the brushes made of black sable almost invariably have better points. The smaller sizes of sable generally used for stippling should not be too small, as working with same would lead to an excess of finish, or rather fineness of stipple, which would materially discount the higher objects of art—viz., depth, solidity, and colour.

We now arrive at the most important part of all—the colours. As

in the case of the brushes, I have ever given the preference to the colours produced by Winsor & Newton. I have never found them vary in quality, and have always found them easy and agreeable to work with. This is more than can be said of all other colours. For very many years I have mostly used moist colours and have always found those supplied me by Winsor & Newton, although they retain their moisture while in the box, dry consistently and in convenient time when once they are applied to paper. These qualities are both very important ones to an artist working, and I feel sure any one adopting their use will derive complete satisfaction therefrom.

We may classify the colours used in portrait painting under two headings—those used in painting the flesh, and those more strictly adapted to painting draperies, background, and other accessories.

The colours mostly used for painting the flesh are as follows:—Chinese white, raw sienna, Indian yellow, Venetian or light red, vermilion, pink madder or rose madder, Indian red, brown madder, cobalt blue, burnt sienna, Vandyke brown.

The colours used for draperies, backgrounds, &c., in addition to those above, are gamboge, yellow ochre, sepia, lake, carmine, French ultramarine, smalt, indigo, Prussian blue.

Chinese White.—This is a most valuable pigment. It is prepared from oxide of zinc. It works well in water, has a good body, and is thoroughly reliable as regards permanency. There is no other white which has been used up to now as a water colour which can compare advantageously with it for these properties. It should, nevertheless, be used with moderation (as a water colour), and preference always given to transparent and pure colours for flesh. There are naturally times when a combination of other colours with white is not only advantageous, but absolutely necessary, but when not so I recommend working without it. As there are many kinds of Chinese whites in the market, I have tried several experiments during the past three years or so to test their various qualities, and have had some strange experiences. As a result, I have found Winsor & Newton's permanent Chinese white far and away the best for working. It possesses all those qualities most essential to its free and successful use without any of the pasty and clogging properties combined with a deficiency in body to be found in many of the other makes. As I say, use it very sparingly, but when used at all, it is invaluable having the best product at one's disposal. It is mostly limited to putting in the white spots in eyes, or the working out of lace, gold ornaments, and such other high lights. If an error should be made, it will be found useful in correcting same, as we will see further on.

Raw Sienna.—A natural earth of yellow colour, and much valued for its delicate transparency. It is a beautiful colour, and a wash here and there in foliage produces great variety and relief. It also combines with pink or rose madders in producing a very delicate flesh, and is generally a good and safe yellow to work into the face, that is, of course, on such portions of it where yellow seems to assert itself.

Indian Yellow.—A beautiful intense yellow possessing greater body and depth than gamboge. Its reputation for permanency is not without doubt, but in its best form may be considered thoroughly safe. Mixed with Venetian red can be used for flesh. Is also very serviceable for draperies, &c., and makes, in combination with the various blues, some beautiful greens.

Light Red and Venetian Red.—These colours resemble each other closely. Light red is one of the most useful of colours. It makes a good base for flesh, is fairly transparent, low in tone, and more of an orange tint than Venetian red. It is most useful in landscape, as combined with cobalt it gives some of the finest greys, and also mixes well with other pigments. Venetian red, although very similar, is less orange in hue, less transparent, and decidedly more powerful in colour than its relative, light red. Like the latter, however, it is thoroughly permanent, either by itself or in combination with other colours.

REDMOND BARRETT.

LIGHT, LENSES, AND STOPS.

(An abstract of a paper read by Mr. John Edmonds at the ordinary meeting of the Birmingham Photographic Society.)

THERE are two theories by which the nature of light and its propagation through space are explained, namely, the corpuscular or molecular theory, and the undulatory theory. According to the first, light consists of minute particles emanating from self-luminous bodies, as the sun, a candle, or a red-hot piece of iron. According to the other, light is produced by waves or undulations of the molecules of an extremely subtle and rarified elastic matter called ether, existing everywhere, and set in motion by the causes which produce light; this is called the undulatory theory, and is now generally received. This ethereal medium is not light, but light is produced in it by the

excitation on the part of luminous bodies of a vibratory motion, similar to the undulation of water that produces waves, or the vibration of air yielding sound. Water set in motion produces waves. Air set in motion produces waves of sound. Ether, that is the theoretical ether pervading all matter, likewise set in motion produces light.

The nature of a vibratory medium is better understood by reference to that which we know possesses the ordinary properties of matter, viz., the air; and by observing the analogy between the propagation of sound and light the difficulties of the undulatory theory become less formidable.

To illustrate vibration, take a small ball attached to a silk thread and suspended inside or outside of a glass bowl, so that it may touch the edge; set the glass in vibration by means of a violin bow producing sound, when the ball will be thrown from the edge and repelled so long as the sound is continued. This must suffice as to the theory of light. We know but little of its nature, but must proceed to consider briefly some of its peculiar properties.

All objects upon which the light falls are either opaque or transparent, but these terms are not absolute. Many objects are only partially transparent or translucent, none are absolutely transparent. We have to use the term a ray of light, but a single ray must be in reality a mere ideal abstraction. In practice we can only deal with whole bundles of rays, the larger of which are usually called *beams*, and the smaller ones, whether parallel or conical, *pencils*. It is, however, convenient to speak of small *parallel* pencils as *rays*, when convergent or divergent they may be designated pencils.

When rays of light fall upon a plane surface, as the flat surface of a mirror, a greater or less number of them are reflected, and the result is in accordance with a definite law by which the angle of incidence, as it is called, is equal to the angle of reflection. This is easily shown by a diagram.

Thus, the angle IBP , formed by the incident ray, IB , with the perpendicular P , is equal to the angle PBR , formed by the reflected ray, BR , with the perpendicular P . This is a simple law, but an important one, and the knowledge of it is essential in the various applications of mirrors and other reflecting surfaces.

When rays of light in their passage impinge or are incident upon and enter a transparent medium or material of a different density, their course becomes altered, and the line of their direction broken, whence they are said to be refracted. If the medium they enter is denser than that through which they were at first passing, they will be refracted towards a line perpendicular to the surface, or, as it is expressed, refracted towards the perpendicular. [This was shown by a diagram.]

Light is not simple but compound, and when a ray is passed through a prism it is divided into the primary colours of the spectrum, viz., violet, indigo, blue, green, yellow, orange, and red—the red, or visual rays, being the least refrangible, and the blue ones at the other extreme of the spectrum having the greatest refrangibility. This was shown upon the screen by a diagram, and afterwards by projecting rays through a prism by means of the limelight, when the brilliant rainbow colours of the spectrum appeared upon the screen. By interposing a double convex lens in the path of the ray, the colours were re-converted into white light.

The lecturer then explained that lenses were of two kinds, viz., positive, convergent or magnifying lenses; and negative, divergent or diminishing lenses—the one enlarging and the other diminishing the image of an object seen through it.

The principal forms were illustrated by diagrams, and described as convex, plano-convex, and concavo-convex, or meniscus positive lenses; and double concave, plano-concave, and divergent meniscus negative lenses.

In all lenses having the properties of prisms, spherical and chromatic aberration are inherent in them, and means were adopted in former times to correct these errors by altering the forms of the lenses so as to diminish the aberration, and by the use of diaphragms to compel the rays of light to pass through the centre of the lens, and thus improve the definition, this method, however, being very imperfect and attended with great loss of light.

Spherical and chromatic aberration were then briefly explained, and diagrams projected upon the screen showing the various forms of

achromatic lenses, constructed of two or more compound lenses made of crown and flint glass respectively, each kind of glass having a different density and refractive index, and the curves being so arranged that the negative aberration of the one counteracted the positive aberration of the other.

This was followed by a description of the achromatic view lens, the Petzval portrait lens, and the more modern doublets, rectilinear, and other lenses used in photography, also of the position and uses of stops to correct distortion, flatten the field, and regulate the sharpness of the image and the time of exposure required.

In conclusion, a series of instantaneous and other photographs were exhibited, taken under varying conditions as to exposure, light, lenses, and stops.

INSTANTANEOUS PHOTOGRAPHY.

It seems a hopeless task to persuade the embryo amateur that he should begin at the lowest round of the ladder and work upwards. He has his mind's eye on horses at full speed "just going under the wire," and kindred subjects. To tell him that the taking of such pictures requires considerable experience in the art of proper lighting and development, places you, in his mind, in the category of those who are still groping in the darkness of wet-plate work.

To commence: The photographer should instruct himself carefully in the use of stops, and then test those he is constantly using in various kinds of lighting. This is a necessity, as on the stop depends the speed at which the instantaneous shutter may be worked to obtain a properly-timed negative. A vast majority of photographers, both amateur and professional, believe that an instantaneous (?) exposure with the shutter is necessarily under-timing. Now this depends entirely on the operator. If, even with very bright sunlight directly on the subject, a very small stop be used, most assuredly the plate has not received sufficient exposure. But, on the other hand, if a very large stop be used, the plate becomes over exposed.

Another matter of great importance is the question of intelligent development. The usual course is to prepare an ordinary developer and pour it over the plate. If it comes up all right the operator has "hit it," and if not, he has "missed it." This may suit those whose only object is to occupy their leisure time, but for the benefit of those whose purse is limited and whose time is valuable, I say *STUDY* development. It is the basis of all good work. I have had plates placed in my hands which have had twenty-five times too much exposure, by actual calculation; but, knowing this fact previously, and exercising care in the development, I have made good negatives from them. But, say you, it is under-exposure, not over-exposure, we are complaining of. To begin with, unless the light is *very* poor, or your shutter faster than any I have yet seen, there is very little necessity for any under-exposure. I have used a variety of shutters, from the simple drop to the latest combination of springs and triggers, and find that with all of them, in a bright, unclouded sunlight, a stop equal to $f/16$ or $f/22$ in the country, or $f/11$ to $f/16$ in the city, gives me sufficient light to capture railroad trains at full speed (three-quarter view), bicycle riders, and other kindred subjects. When I say sufficient light, I mean sufficient exposure for the production of a good negative by any one of average experience in development. I think a majority of the failures may be attributed to the idea which the average amateur seems to possess, that a lens advertised to take a 5×7 landscape must necessarily take it instantaneously. I find that for 5×7 instantaneous work, an 8×10 size of lens is about right, and am using myself a No. 2 Euryscope for that class of work. But suppose that the negative is, for example, under-timed. Did you ever try hot water to develop it? No? Why not? No, it won't melt the film if the plate is cold. An experiment recently made has shown that a warm plate will melt with ice water for development, while a cold plate is unaffected in this respect by developer quite hot. Do not imagine, however, that it must burn your fingers, for there is a limit even to this. This warm-water treatment will frequently bring out the most obstinate cases of under-exposure. However, if it does not, why soak the plate awhile in water and some sal-soda until the film is wet through. Then pour off and add your developer—tepid, however, this time. Do you catch the idea? Yes? Well, try it.

BLISTERS.

THE season of the year reopens the discussion of blisters. It will not be denied that it is a subject worthy of consideration, of thorough examination, of close observation, and of careful study as long as there is any doubt as to their cause, as to the conditions under which

they are likely to occur or not to occur, and as to the remedy or remedies which may be used to prevent them.

As to their cause: The immediate cause of blisters is *carbonic acid gas*, generated by the action of the hypo on some compound, *nit* determined, which is probably formed in the operation of printing. That blisters are caused by carbonic acid is proved by taking a wide-mouth bottle half filled with pure lime water; put into it a sufficient number of large, well-filled blisters, which should be detached from as much of the superfluous paper as possible. Break the inflated gas bags under the lime water by means of a glass rod. The bubbles of gas will rise to the top of the water, but as the gas is heavier than the air it will remain in the bottle, floating on the water for a short time, although not visible, the same as oil would do, while the air will be crowded out to give it room. The bottle should now be tightly corked to keep the gas from escaping, when, after shaking, the lime water will assume a milky appearance, due to the formation of carbonate of lime in the solution. This is exactly what will happen if carbonic acid obtained in any other way—from marble, for example—be mixed with the lime water. Moreover, if a few drops of hydrochloric acid be added the milkiness or precipitate will disappear in one case precisely as in the other. Undoubtedly carbonic acid is the cause of the precipitate in each case, it being obtained from the blisters in the one, and from the marble in the other.

Under what conditions are blisters most likely to occur? First, they are more likely to occur in warm weather than in cold. This is so generally recognised that the summer months are, by common consent, called "the season of blisters." Second, the condition which I believe to have the most powerful influence in producing them is an old silver bath surcharged with organic impurities.

When albumenised paper is floated on a new, strong, silver solution the latter renders the albumen insoluble, forming the albuminate of silver, but at the same time the silver solution redissolves a small portion of the albuminate, just as a strong solution of common salt precipitates the so-called insoluble chloride of silver and then redissolves a portion of the precipitate, and just as the negative bath redissolves a portion of the iodide of silver, which it precipitates.

Every time a sheet of albumenised paper is silvered a little more of this nitro-albuminate of silver (if this is the right name) is added to the bath until it can hold no more. At this point its ability to produce blisters appears to be at its maximum.

In addition to the above predisposing causes, it is proper to say in passing that an often-used hypo bath is more likely to produce blisters than a fresh one, and that paper silvered for some time previous to being used frequently shows, when the trouble is epidemic, a stronger tendency to blister than that freshly silvered.

I have nothing to say about bad paper, musty, mouldy, partly decomposed, or otherwise unsanitary. I refer only to conditions under which strictly first-class, sound, healthy, highly albumenised paper is liable to be affected by the malady. Nothing is better known by dealers in photographic supplies than that the best paper in the world is sometimes sent back, loaded with maledictions as loud as they can be produced in black and white, as unfit for use, all on account of its atrocious blistering propensities, while another will find the identical paper highly satisfactory, and in all respects worthy of commendation. Cause: probably a large excess of nitro-albuminate of silver in the bath of said complainant.

Let it be borne in mind that the bath may be thoroughly sunned without ridding it of this impurity. A strong silver solution strongly charged with it will often remain clear in the sun for days, and the printer may therefore presume that his bath is in fine working order; prints look fine and brilliant, tone beautifully, when lo! after fixing, the blister plague breaks out in malignant form—batch ruined. Another trial with some little modification, read about or heard of; result, surprisingly similar.

Right here is an opportunity for a neat little experiment. You have all read that if you have your albumen thoroughly coagulated you will have no blisters. Probably I thought so once myself. Whether I did or did not, it is a mistaken notion all the same. If your bath is sixty grains strong, and the prints blister almost or quite unpreventably, no matter whether you leave the paper on it two, three, or six minutes, just reduce its strength to forty grains, and sun it a few hours. Then laugh or weep as you feel most like doing, when you miss the jolly faces of your dear familiar pets from your next batch of prints.

But the best way to treat your bath when it gets into this condition is to boil it down and carbonise the organic matter. Do it well while you are at it. This can be done with an oil or gas stove and a porcelain evaporating dish. The latter need not be very large, one that will hold two to four quarts being sufficient. It is not necessary that it should hold the whole, or even half, of the solution at once; this

can be added, with a little care, from time to time as room is made for it in the dish. When the water is boiled out, and nothing remains but a frothy mass, the heat should then be continued, stirring the mass with a glass rod until it settles into a quiet and liquid state. It is now fused nitrate of silver. In doing this there is danger of breaking your porcelain dish if it is placed where there is a draught of air from any window or door. It is a puff of cold air, and not the heat alone, that breaks the dish. It is safest not to turn off the heat suddenly. When cool, redissolve and reconstruct your bath.

Even with a good bath there is in the summer months, and other months also, a margin more or less in width available against the entire exclusion of the pest. In my own mind I have no doubt that the compound from which the hypo bath liberates the gas which makes all this trouble is due to the oxidation of the albuminate of silver, that this oxidation takes place to a greater extent in some states of the weather than in others, and that when the bath contains this albuminate in solution a portion of it is transferred to the paper, increasing the supply of the material from which the gas is produced, and, as a consequence, a more liberal supply of blisters is formed. But this last is speculation, which, though based on facts observed, is not proved.

The facts, however, remain. In practice the cause of the difficulty cannot be wholly removed; we must therefore have recourse to some means of preventing the formation of the blisters, even when the gas is present. This is most effectually accomplished by the liberal use of common salt. I do not mention this as an item of news, but because so many other ways are brought forward as better. As nothing can be simpler, cheaper, easier to use, and, at the same time, more thoroughly reliable, so nothing is likely to supersede it in the hands of experienced photographers. Let any one who doubts its merits dissolve a pound of this cheap article of household use in a gallon of water, transfer his prints into it from the fixing bath, then let them remain ten or fifteen minutes, then make the change from salt to plain water by letting the latter run on to the prints while the other is drawn from the bottom of the vessel through a siphon. Unless he has an incredibly desperate case on his hands, his prints should be entirely free from blisters.

A little ammonia in the fixing bath acts towards the same end; likewise carbonate of ammonia, which may be used much more freely without endangering the brilliancy of the albumen surface.

The conclusion of the whole matter—blisters are preventable accidents.

W. H. SHERMAN.

—*Con. Number St. Louis Photographer.*

THE INTELLIGENT USE OF THE DETECTIVE CAMERA.

[A Communication to the Liverpool Amateur Photographic Association.]

SEEMING that most amateur photographers nowadays either possess or are about to possess a detective camera, and this being the season of the year when it can best be used, I thought a few words on the subject might be acceptable to some, if not all, of you. There are so many various kinds of detective cameras now in the market for the amateur to choose from that it would be impossible for any one to say which is the best, as most of them have all and every movement that can be required, the chief difference being that some are more convenient to use than others, more notably one lately brought out by one or two members of this Society. This, however, is not so important a factor as knowing how and when to use the camera for its special purposes. As I am anxious not to weary you, I will commence by calling your attention to some of the advantages, as well as disadvantages, of this class of photographic work. As to the former, it is well known that its chief characteristic is *concealment of purpose*, thus enabling the operator to obtain "shots" at bits that probably could not be obtained with the ordinary uncovered camera, even though the same be held likewise in the hand. Again, the detective camera is very conveniently carried, always set up, and ready for an exposure. And last, but not least, we can alter the stop of the lens or speed of the shutter in less time than it takes one to write it. Many persons seem to think that this is all that is needed to enable them to take any kind of picture. That this is far from correct is only too painfully understood by the thoughtful worker.

When speaking of instantaneous pictures, Mr. H. P. Robinson says: "Instantaneous pictures of a sort have become so easy of accomplishment that our exhibitions are flooded with them. The photographs may be very useful to painters, because they are real bits from nature—real machine views, at least; but they are not art. Yet if you look through an acre of them you will find every now and then you will come upon a gem."

On looking through my work done with the detective camera, I have

noticed that the greatest failures arise from bad focussing, or shake of the camera when pressing the trigger of the shutter. Of course there are other faults, such as, that some of the subjects were not worth taking; but then this applies to nine-tenths of photographic work, let it be with the detective or field camera, it matters not which.

Focussing.—This is a most important matter, for however good otherwise the picture may be, if it is not in good focus then it is practically useless for enlarging from or making lantern slides, whilst as a print it is anything but satisfactory. On looking over the many faults and errors made by myself and others, I find that, perhaps, quite twenty to thirty per cent. of the exposures made are, to more or less extent, faulty in this respect. In some price lists of lenses we are told that a certain lens of six-inch focus will define sharply all objects over nineteen feet away, when using the lens at $f-8$. That this is not borne out by my $5\frac{1}{2}$ -inch Wray lens there can be no doubt, for with $f-8$, and keeping the distance reasonably sharp, the objects in the foreground to be in focus must not be nearer than forty feet, whilst with $f-5.6$ neither I nor a photographic friend can get any sharp focus at all, thereby showing that this power, as a working one, is purely imaginary. We are also told by experts that the depth of definition of a lens is governed solely by its length of focus, or, to put it in other words, that all lenses equal in focal length have the same power of depth of definition. This then being so, it can be easily understood why a lens of comparatively short focus (that will cover the plate well) is the best for use in the detective camera, for its real value and suitability lies in its power of giving great depth of definition, which is so valuable in a picture. This then brings us to the question, What is the proper focus, say, for a 5×4 plate? Having worked two lenses on this sized plate of $5\frac{1}{2}$ and $8\frac{1}{2}$ inches focus respectively, I find that the best focus for general use is one not over 6 inches, not even excepting shipping work, which is usually considered to require long-focus lenses. Of course, if you cannot get near enough to the objects, then a long-focus lens is a necessity. Many of you use finders with your detective cameras, I do not, as it requires but very little practice to enable one to know the angle the lens gives; besides, how can any one snap his shutter at the right moment unless he is carefully watching the object instead of looking at a finder, which gives so small an image that makes it practically impossible for him to see the various changes properly. If I do use a finder it will be for the purpose of obtaining a finer focus of the objects exposed upon. For instance, I would first place a man just sufficiently far away from the camera as would with say, $f-8$, or other stop in general use, give me the man and extreme distance equally sharp. On the ground glass of the finder I would then mark in parallel lines the length of the man; I would then place him at a nearer point, and again show the length of the man on the ground glass, and so on, until the man was of such a size that it would be unwise to proceed further on account of the great lack of depth obtainable in the picture. About three different sizes would be found sufficient. And now another matter may be mentioned; when working with very large apertures, pictures are often found faulty in focus on either the margin or middle. Now this is not always the fault of the lens, but of the worker, for two persons may work with the same lens and stop, and on the same view, yet one picture may appear better focussed than the other, for while one focusses sharply on the centre of the plate, the other does so on the whole of it, and thereby obtains sharpness generally.

To illustrate this, I will ask you to look at this group taken on board ship. You will notice how sharp the persons in front are, whilst those at the back and sides are far from sharp. The stop used was $f-16$, and this one might have thought would have brought all into focus, but no; the picture has been spoiled by my not focussing a point further off which would have brought the two sides of the picture into better focus, and thus have equalised the focus all over the plate, which the lens would do if properly used. Therefore, when I determine an object to be in focus at, say, five yards distance, I choose that it be only just in focus, and thus throw the difference on further objects into focus at the same time also. It is only by careful attention to these trivial points that the detective camera can be used successfully, not to say intelligently. And now we come to consider how the camera should be held when the plate is being exposed. Some, or perhaps I ought to say most, people hold it under their arm, at the same time peering into the view finder. I myself prefer to bring the camera up in front of me, and whilst keeping my eyes fixed on the object, waiting for the correct moment to press the trigger. I may here mention that some time ago I developed some instantaneous shots for a professional friend (or, I should say, dealer) who did not like to risk spoiling the plates himself, as they were for a customer who was an artist. They were all views of fishing-boats and men, and I think I never saw such a capital collection of incidents. Somehow or other the figures were all caught at the right moment, neither too soon nor too late.

Quoting Mr. Robinson once more, he says:—"Nothing but a sound knowledge of those laws and constant practice will enable a photographer to make the immediate and lightning-like application of them which is necessary in instantaneous photography. In photographing scenes containing groups of figures, the best artists will get the best pictures. A photographer without a knowledge of art would simply 'fire into the brown of them,' as a sportsman would say, and trust to luck; while a photographer who knew something of the rules of composition would wait until his figures arranged themselves to advantage, and would know when was the best moment to pull the trigger of his camera."

Development.—After many trials of different developers for instantaneous work I decidedly prefer the following, namely:—

Sulph. pyro.....	20 minims.
Saturated solution soda	90 "

to each ounce of developing solution.

The sulph. pyro referred to is that made by Messrs. Sharpe & Hitchmough, of this city, which is said by them to contain one grain of pyro in every ten minims of solution. The saturated solution washing soda is made by putting into a jug a pound or so of the soda, and then pouring over it a small quantity of boiling water, after which the saturated solution is poured off and then filtered into the stock bottle. When quite cold crystals are formed, clearly showing that the solution is really a saturated one. I use no bromide whatever, as I have not found it at all necessary, even with plates over-exposed in the ordinary camera. As an instance of this I may mention that not long ago I gave a 10×8 plate eleven seconds with *f*-11 stop on an open landscape, and developed the plate with the maximum quantity of soda, and I neither got fog or flatness of image, because, as soon as I noticed the image flash up, I quietly made up a fresh developing solution with plenty of pyro in and no soda, then poured off the first developer and applied the latter, which quickly gave me the density, or rather, I should say, gradation, desired in the negative. With the detective camera all the plates, being under-exposed, require forcing in development, therefore I would advise that on no account should the pyro be at any time stronger than 20 minims to each ounce of developer, as, if so, the resulting negative is certain to be too hard or chalky, a disadvantage which afterwards cannot well be remedied, whilst a thin negative is always capable of being improved by intensification during development, or even after being fixed. The importance of keeping back the pyro cannot be too strongly put before you, this, and not the accelerator, being the key-note of the resulting negative.

Plates.—Those I prefer are Edwards's Isochromatic. My reason for this is (1), they are better coated; (2), trifle more sensitive; and (3), more suited to the ever-varying conditions of light than any other plate in the market. If expense is an object, this may be met by being more particular as to choice of subject, and thus expose a less number of plates, or when changing the double backs have half only of those mentioned and the other half either Fry's or Ilford Ordinary, using the latter when the light is at its best. That this is an important point in detective camera work I will prove to you by the four negatives I now pass round for inspection. The plates used were Wratten's Special Extraordinary, time of exposure about 6.30 in the beginning of June; light, bright sunlight, but very yellow—so much so, in fact, that do all I would I could not get density even in the sky, and yet where the whitewashed or painted roofs of the warehouses and the white sails of the boat come in these are dense enough. I am certain that had these plates been Edwards's Isochromatic I should have obtained a much better quality of negative. In dull or cloudy weather also, isochromatic plates are much more sensitive than the others named, thus enabling the operator with these plates to obtain detail in his negatives that would without doubt be lost if the cheaper ordinary brand of plates were used. There is also another advantage these (and, indeed, Carbutt's and other expensive plates) have over the cheap brands, and that is the ease with which they will re-develop up to proper density after all detail is got out of the plate. This is a most important factor, inasmuch as all plates used in the detective being under-exposed. This allows us to first develop out all detail, after which the pyro may be added, and a negative made that will do for silver or other printing, as the operator wishes.

Shutters.—The form of shutter I use is, as you see, a "Kershaw," the release being a press button. I don't know that this can be beaten, as unlike the string and other arrangements for this purpose the release does not jerk the camera. I do not, however, find the Kershaw fast enough for athletic sports or racing subjects, but as I am not anxious to make *silhouettes*, but pictures, the speed is all I require. I would, however, prefer a Thornton Pickard "time and instantaneous" shutter if I were buying another one, it being, I think, a faster, and certainly more generally useful article. Referring again to speed of the shutter, unless the

objects are very close and large, about eight turns of the tension spring is quite sufficient, my object being to get the maximum of exposure consistent with the non-blurring of the objects in the picture. I confess to a liking for a small amount of blur in street pictures, as they give some idea of motion, and do not look so stiff as when without blur or absolutely sharp. The distance of the subject must rule the speed of the shutter. If very close the speed must be great, but if reasonably distant then a few turns is all that is required.

In the foregoing I have dealt with my method of working the camera, and must now confess that the results of detective work are far from being satisfactory, or all that can be desired. I honestly believe that it, in one way or another, costs more, or at least as much, as working a whole-plate, and then what is the average of good work? It is almost fearful to contemplate; but, of course, some persons may be so easily satisfied that they put all their negatives down for gems, provided they give a print at all. As an instance of this, I remember reading in a photographic annual an article written by a well-known amateur, who claimed for a certain picture he had taken that the principal object was quite sharp and full of detail, whereas, having seen a print from the negative, I find that—(1), the object is not even in proper focus; and (2), it possesses little or no detail whatever. The latter I do not find fault with, as such a speed of the shutter must of necessity not admit of much detail being secured. It may be thought clever to photograph trains quite sharply running at the rate of, perhaps, fifty miles an hour, but, at any rate, it is not art. It would be interesting to criticise some of the many pictures which some writers speak so glibly of in our photographic journals. I am afraid the gilt would fall off some of them if carefully analysed.

And now, in conclusion, those who intend going in for detective work need not despair of success in the highest degree, provided they will work it in an intelligent manner, or, in other words, not expect their machine to do all that is requisite, but use their brains also. H. WILKINSON.

NOTES FROM NEWCASTLE.

THE approaching visit of the British Association is beginning to absorb public attention. It should have special interest for local photographers from the fact that Captain Abney is the President-Elect of the section Mathematics and Physics. Captain Abney has done, and is doing, such good, sterling work in connexion with the art-science, that I really think some effort might have been made on the part of the local devotees of the art to give him a suitable reception. The only local photographic society, as far as I am aware, is doing nothing in the matter; but I suppose it would be too much to expect this moribund body to do anything of importance.

Various handbooks have been published in connexion with the visit of the British Association, amongst others, an *Official Guide to the Industries of the Tyne and District*; an excellent paper on photography being contributed by Mr. Edwin Dodds. I don't know that I should have considered Mr. Dodds an authority on this matter any more than a dozen or two other gentlemen I could mention, but I must say, after reading the paper, that for good taste, expression, and as a clear and simple statement of progress, nothing could be better.

Mr. W. W. Tomlinson's comprehensive guide to Northumberland is a most excellent and interesting work, and should be on the shelves of every member of the craft in the county. Mr. Tomlinson divides the county into sections, e.g., Newcastle, Hexham, Morpeth, Rothbury, Bamborough, Alnwick, &c. &c. Every town and village of any interest whatever is described for the full benefit and information of the antiquarian, artist, and botanist; all the hills, loughs, crags, churches, ancient British camps, castles, and pell towers, the Roman wall, stations, and camps, ruined churches, chapels, and monastic houses, being properly described in due order. In addition to proper directions as to route, Mr. Tomlinson does not forget the hotels and places of accommodation for travellers. I would like to see every county in England and Wales treated in the same comprehensive manner. I have already heard of two amateurs who are now "doing" Northumberland on the lines laid down by Mr. Tomlinson.

Newcastle just now is certainly well supplied with photographic material, no less than five chemists now dealing, more or less successfully, in apparatus, &c.; and for prices I should say nowhere are they lower. Schering's pyro, in one ounce bottles, at 10s. 3d. a dozen; hypo soda at 7s. per cwt. cask; and fifteen per cent. off list prices for Lancaster's cameras, &c., is pretty good cutting. This sort of thing may easily be overdone; but I saw in one shop an enlarging lantern, with six-inch condensers and front lens, &c., at 6l. 6s., an exact counterpart of one in a London list (just received) without front lens for 9l., which shows that some of our retailers make big profits.

Returning by tram the other day from a short photographic excursion, I was honoured with some friendly confidences by the conductor, who, presuming upon my "legs," informed me, amongst other family details, that he also was a photographer, and had been out at the Cape, where he used a 15 x 12 camera, and had taken some excellent views for the Government with one of Dallmeyer's aromatic triplets!

EIKONOGEN AS A DEVELOPER FOR BROMIDE OF SILVER PAPER.

(Abridged.)

EVERY one who has experimented with bromide of silver paper will agree with me that iron oxalate, the developer hitherto most generally employed, although giving on the whole fairly good results, is not free from certain drawbacks. Among these I may mention the yellow iron spots which, in spite of the most careful manipulation, cannot be prevented from occasionally making their appearance, and the expense entailed by the considerable quantities of this reagent necessary for developing prints of large size. Another inconvenience, to which, however, we have almost become accustomed, though that fact does not diminish the annoyance, is the soiling of fingers, measuring glasses, dishes, &c. Some persons have sought to substitute hydroquinone for iron oxalate, but as far as my knowledge goes this reagent is not generally adopted for developing positives. At this I am not surprised, for the development with hydroquinone, which is very gradual, occupies a considerable time, and at the present day time is more valuable than ever. Many, too, have probably been deterred from employing hydroquinone by its high price. For whatever may be said in favour of the repeated use of the same developer, I have only been able to obtain really good contrasts of light and shade, with clear "whites," by using a perfectly fresh developer, and applying it only once. Iron oxalate is therefore still, even at the present day, in common use in spite of its defects. It seems, however, probable that it will in a short time be completely superseded by eikonogen.

The directions issued by the manufacturers of the latter reagent state that "old developer" should be employed to bring out the image, and fresh solution to intensify. I already stated some time ago, in the *Deutsche Photographen Zeitung*, that my experience showed that the results thus obtained were not very perfect, except in the case of over-exposed plates, when the best method of working is to commence with old developer to bring out the lights, and to finish off with fresh.

It is otherwise in developing positives. Here the developer, when made up according to the receipts given, acts much too energetically, and attacks the whites even after short exposure, producing, however soon one may stop the development, a monstrous, ineffective sort of image. As the composition of eikonogen is at present unknown, I didn't venture to alter the make-up of the developer, but contented myself with simply diluting it. In my experiments I employed Eastman paper, which, being of medium sensitiveness, enabled me to hit off more regularly the proper length of exposure. The developer when diluted certainly gave a better image, though it was still much inferior to that obtained by oxalate after similar exposure—the whites being hard and chalky, and the shades having an unpleasant green tinge, which neither a bath of water with three per cent. acetic acid, water acidulated with hydrochloric acid, or the alum bath, could get rid of. The addition of bromide of potash increased the hardness without imparting a good black to the shades.

As there seemed little prospect of improvement by continuing in this course, I experimented with a developer that had been already used, selecting one which had been employed for the development of a negative. The result was immediate and astonishing. Without any addition, without any dilution, I obtained an image with pure black shades, well modulated half-tones, and clear whites, in the softest and most harmonious gradation. The lighter half-tones especially showed a delicate silver-grey, such as one but seldom obtains with iron oxalate, and in the case of highly sensitised paper only when one has taken enormous pains to hit off the exact period of exposure. I developed three more positives that had been exposed for the same length of time in the same portion of developer, and obtained equally satisfactory results. After a variety of experiments, which space here keeps me from enumerating, I believe myself to have established the following method of procedure as the most satisfactory, and venture to recommend it herewith.

I make up the developer according to the directions given in the prospectus, and employ two different solutions. For each negative I take a fresh quantity of the developer and filter it, after finishing the development, into a long-necked flask, provided with a ground-glass stopper, which is always to be kept tight, that the liquid may, as far as possible,

be protected from the action of the air. Of course, developers to which bromide of potash has been added must be kept separate. This flask I mark "1." To bring out the image, the paper, after exposure, is softened by immersion in water as usual, and after the water has been poured off a suitable quantity from flask 1 is added. When the time of exposure is right the image is developed at such a moderate pace and so regularly that one can control the process excellently. When sufficient intensity has been obtained the developer is poured quickly off into flask 2, and the print in the dish rinsed repeatedly with water. Acidulated water is unnecessary; the image being fixed in the ordinary way with five per cent. soda solution; a subsequent alum bath is also unnecessary, as I have never found that crumpling takes place. The developer in flask 2, if kept well stopped, can be employed over again several times. I have gone as far as developing five different prints with the same solution, though I remarked that the development took place in the case of the last ones rather more slowly; the tone and the whites, however, remained satisfactory in all cases where the development was not in fault. On exposing a little too long, and developing with a solution employed several times before, the image attains a warm sepia tone that, though unsuitable for enlargements, imparts to landscapes a very charming effect.

I possess no data as to whether the developer permits of being subsequently regenerated, as my knowledge of chemistry is not sufficient to enable me to carry out experiments of this kind. Whether this should turn out to be the case or not is of very little importance, as the developer has in any case done its duty to the full. After drying, the photographs developed with eikonogen display a delicate silky brilliance that I have not hitherto seen obtained with gelatine paper.

A further advantage of this process, which should not be undervalued, is its great cleanliness—neither hands nor utensils being stained in the least, and no yellow spots appearing on the paper. That the developer in time becomes brown, as also the soda bath, after frequent using, does not affect the process in the least.

Above all, its extreme cheapness must not be left out of consideration. The price of eikonogen is 25s. per kilo (about 12s. per pound), at which many of my readers will probably shake their heads; but examine the figures. To develop a photograph 75 x 100 c.m., for example, one requires at least one litre of mixed oxalate developer, the cost of which is at least 60 pf. (7d.), and this can only be employed for one print; now the eikonogen developer not only costs nothing at all, since it has already paid for itself in developing negatives, but can also be employed over and over again. It may perhaps be objected that with pictures of this size the price is generally such that a small saving is scarcely worth considering; but he who does not reverence the penny will not soon be in a position to invest in the funds, and in a large business the saving is worth considering.

All things taken into consideration, I am of opinion that the new developer is destined soon to gain for itself a large number of friends, and this will be the case still more whenever it throws off its mysterious incognito, and appears before us either as an old acquaintance or as a new edition of the egg of Columbus. For the thoughtful operator there is always something unpleasant in working with unknown reagents, even when they possess such excellent qualities as eikonogen.

—*Deutsche Photographen Zeitung*.

C. HINCKELMANN.

THROUGH JAPAN WITH A CAMERA.

CHAPTER XI.—Nikko (continued)—THE JAPANESE LANGUAGE—JUSSENI—YOMOTO.

AT Nikko I was thrown on my own resources in the matter of language, and the Japanese language is a fearful one for foreigners. It is, in fact, a language that no foreigners really learn, except a few who make the learning of it their sole occupation for years, and even these get expert in it only if they are naturally good linguists.

There are two distinct languages, the written and the spoken, besides many variations of both of them. It is the latter that the foreigner generally tries to learn, and fails. Even it alone is probably about as great a task as to learn five or six European languages. One peculiarity of the language is the use of "honorifics." This means that every word, besides its own peculiar meaning, expresses the humility of the speaker, or his respect for the person spoken to, or conveys an opposite meaning. Besides this honorific modification of ordinary words, there are special honorific words and particles, and when a Japanese wants to be remarkably polite he dilutes all his ideas with these honorifics.

To take an example of what I mean by words having, besides their own meaning, a honorific significance: there are no less than twelve Japanese words for our word "wife." These words are all different, and represent a graduated scale of politeness. Of the first, or least polite of all, the

dictionary maker quaintly remarks that "A man may use it to his own wife, or to others to whom it is not necessary to be over polite."

The Japanese learn foreign languages with wonderful facility, considering the difficulties that are in the way of them. The greatest of these is that they have to learn a number of new sounds. The Japanese language is syllabic; that is to say, it is made up of a number of syllables—about seventy—each consisting of an initial consonant and a vowel. There is only one final consonant, namely "n," and those who have not been specially trained in foreign languages cannot pronounce any word which is not made up of these syllables. The result is sometimes curious. Thus, the one English expression which is known almost all over the country, "Good-bye," is generally pronounced "gooroo-bye." Foreigners find it necessary, as a rule, to adopt modified names with the uneducated natives. I am tolerably fortunate, as they can come as near my name as Booroton. An unhappy German, who has recently come to Yokohama, and bearing the unfortunate cognomen of Kuchler, has had his name Japanified into "Kokirooroo!"

Sometimes English inscriptions are put over the shops in the larger towns. Some of these are curious, being evidently constructed with the aid of a dictionary. Thus, there are in Nikko two shops owned by the same individual. One has printed over it "Root Store," the other "Diverging Shop;" evidently intended for "chief store" and "branch establishment." Sometimes phrases which must have been picked up orally are used as words with very strange results. One such case I remember is so very remarkable that I may give it. I relate the incident precisely as it occurred, but lest some of the expressions be considered too strong for the British reader, I must ask the Editor carefully to read the tale, and, if he considers it necessary, to introduce a judicious blank or two, so that, leaving the meaning clear, the eye may yet not be offended.*

I was conversing with a Japanese lady—or it would be more correct to say I was attempting, through the medium of my few miserable scraps of Japanese, to hold converse with her. She had shown no symptom of knowing or imagining that she knew any word of English till reference was made to a certain man, when she made the following astonishing statement, all in Japanese excepting the astounding compound adjective, "Oh! I don't like him; he is a God-damn-you-a-disgrace man!"

One understands readily enough, it being predicated that "shito" is the Japanese for man or men, how English sailors in Yokohama come to be designated "Damn-your-eye shito," but as to how the wonderful phrase given above was incorporated into the vocabulary of the Japanese lady as an English adjective, affords much food for unsuccessful speculation.

At Nikko is a very old bridge—three or four hundred years old, I was told—which is closed to the public. It is said that it is reserved for the use of the Mikado, and of certain other great personages. I consider it remarkable as exhibiting a peculiarity of Japanese structures. The upper part of the bridge is of wood; the supports are of stone. The Japanese are not a mechanical people. I don't mean to say they are not clever with their hands; they are exceedingly so; but they are not a mechanically inventive people, and when, in their structures, they came to adopt stone in the place of wood, they retained precisely the old shapes, as seen in the case of the stone supports of the bridge shown in the photograph. Apparently they were ignorant of the principles of the arch until it was recently imported from the West.

The Torii was undoubtedly originally always made in wood, and it will be noticed that the form is one well adapted to a wooden structure. It is still most frequently made of wood, but is often made of stone, and occasionally of bronze; but of whatever it is made, the form is kept precisely the same. This is not, I believe, because the precise form is one which has religious significance, but simply because the Japanese have not the mechanical instinct which induces Westerners to adopt a change in the form of a structure to suit any change in material which may be made.

From Nikko it is a glorious walk to a great lake, called Jusenii, and further to a hot spring village, named Yomoto. The walk is through a deep valley with a steep ascent from Nikko to Yomoto, 3000 feet, or thereby; and there are in the valley some of the most glorious waterfalls that I have ever seen, a river at places leaping clear over a precipice of three or four hundred feet high into a deep and gloomy gorge below.

I did not photograph any of these. I saw many photographs of them in Nikko, many excellent, but none that conveyed any idea whatever of them to one who had not seen them, and, to tell the truth, I believe that photography is not capable of giving an idea of them.

W. K. BURTON.

* It is surely a curious case of folly, this which permits the use of an "improper word" in print if part of it is represented by a blank, although the meaning remains as clear as if the word were written in full. I believe it has its origin with the sensitiveness of writers. They find it necessary occasionally to make use of such a word, but are in terror lest readers should suppose them so lost to all sense of decency as not to know that it is a bad word. They therefore adopt the use of a blank to indicate to the same readers that they (the writers), although they have to use a naughty word, are fully aware that it is such.

RECENT PATENTS.

APPLICATIONS FOR PATENTS.

- No. 15,892.—"Improvements in Photographic Dark Slides." R. W. THOMAS.—*Dated September 3, 1889.*
No. 14,126.—"A Combination Camera Stand and Case." F. BARR.—*Dated September 7, 1889.*

PATENT COMPLETED.

IMPROVEMENTS IN CAMERAS AND IN TRIPOD STANDS FOR THE SAME.

No. 13,868. JOHN WILLIAM RAMSDEN, Park-lane, Leeds, Yorkshire.—*August 17, 1889.*

THE object of my invention is to facilitate the setting up and the manipulation and adjustment of the camera, the closing or packing up of the camera, also to render it more convenient or compact for transport, and to increase the capabilities or capacity of the apparatus.

My invention refers, in the first place, to improvements in the construction and fittings of the base or bed-piece of the camera. Such base or bed-piece is formed as is usual in two parts, the one which is clamped to the top of the tripod stand being capable of being slid along the middle or centre part of the other to which the camera back is attached, or, more strictly, the latter is capable of sliding over the former when the same is attached to the top of the tripod stand. This outer sliding portion just referred to is provided with two longitudinal (i.e., in the direction of the sliding motion) slots or slits, through which pass the screws or studs for securing or clamping the back of the camera in position. The two portions of the base-piece are secured in their relative positions (to which they may have been adjusted) with regard to each other by the same screw or clamp by which the inner portion is secured to the top of the tripod stand. The final adjustment to focus of the camera back is effected by sliding the above-mentioned screws or studs in the before-mentioned slots or slits. These slots or slits are somewhat wider than the portion of the studs or screws passing through them, which allows the camera back to be inclined slightly towards one side or the other.

Secondly, to the attachment and fittings of the camera back. The camera back is not attached directly to the base or bed-piece, but is hung or hinged to a metal carrier, this latter being securely clamped to the base or bed-piece by the screws or studs. A slot in the carrier and a pin or screw passing through the same into the side of the camera back, limits the swing or inclination to the vertical of the camera back.

The frame of the image or focussing plate and also the dark slide are secured in the camera-back frame by means of short hinged plates, which are turned across the two top corners of the frame of the image or focussing plate instead of being slid along grooves.

The front side of the camera-back frame is provided with spring clips for holding the camera cloth or screen.

Thirdly, to the mode and means for inserting or holding the plates in the dark slide. The plates are inserted in the dark slide from the front, by inserting one end or edge of the plate in a groove provided preferably in the top side of the dark slide. This groove is provided with two or more springs, which yield when sufficiently pressed, allowing the bottom end of the plate to be pushed back flat into the slide, when the springs just mentioned force the plate, so that the same or bottom edge of the plate enters a groove provided therefore in the corresponding bottom side of the dark slide. This groove, however, is not sufficiently deep to allow the first-mentioned edge of the plate to pass beyond free from the groove containing the springs.

Fourthly, to improvements in the lens attachments. The front piece containing the lens is arranged capable of fitting sliding in tightly-fitting slides or guides at the front end of the camera box, and is attached to a pillar (D-shaped in cross section), which latter fits and slides in a corresponding hole or socket at the front end of the inner base or bed-piece, in which hole or socket the pillar can be secured at any desired height up to the extreme length of the pillar. The first portion of this arrangement allows the flexible sides of the camera box to be conveniently folded back for packing up, whilst the latter part of this arrangement allows of the lens being fixed close down to the base or bed-piece of the camera, or fixed at any height up to the extreme length of the pillar. This arrangement allows of the camera being readily and properly adjusted in many situations where it would be difficult, if not impossible, to obtain a proper adjustment with the tripod stand alone.

Fifthly, to the form or shape of the dark slide (which is usually arranged to take oblong plates), but I prefer to make the same square, and to take an exposure with the largest possible square field of view, the impression being printed from part only or the whole of the plate, so as to give an upright, oblong, circular, or square picture, as may be deemed to give the best effect.

Lastly, my invention refers to a special construction of the tripod-stand legs. As is usual, the lower half of each is made capable of sliding over or within the upper half, but according to my invention the lower half as well as the upper half is split, the two portions of the lower half being hinged together near the bottom. The split portions of each leg can be opened out and tied across by means of a hinged bar or bars fixed at any convenient height, preferably near the brass or metal slides connecting the upper and lower portions of the legs.

The claims are:—1. A base or base-piece formed in two portions, the one sliding outside the other and provided with slits or slots for facilitating the adjustment of the camera back to focus. 2. The arrangement and use of a swing carrier for supporting the camera-back frame from the base or base-piece so as to be capable of adjustment. 3. The combination or arrangement of lens plate and pillar attached thereto—with slides or guides attached to the camera box or bellows, the former capable of sliding in the latter so as to facilitate the closing or packing up of the camera. 4. The means herein set forth for adjusting the camera-back frame about an horizontal and an imaginary vertical axis with respect to the base. 5. A lens plate attached to one end of a flexible camera box or bellows and connected by a sliding connexion to the base. 6. The combination of lens plate and pillar with a socket in the base-piece for the

purpose of adjusting the height of the lens above the base. 7. The arrangement of grooves in opposite sides of the dark slide, one of such grooves being provided with springs, all substantially as described and shown and for the purpose specified. 8. The means substantially as described and shown for securing the dark slide or focussing plate in the camera back, consisting of hinged plates at the top corners and a recess (or projection) in the bottom of the camera back, with corresponding grooves or slits in the corners, and a projection (or recess) on (or in) the sides of the dark slide or focussing plate. 9. A base or base-piece formed in two portions, the outer portion, which slides over the inner, formed in two pieces connected together at one end by a broad flat plate, and at the other by a hinged cross-piece, substantially as described and shown. 10. A tripod stand with the legs constructed in upper and lower halves, the one capable of sliding over the other or within it, both halves being split, the split portions of the lower halves being hinged together at their lower ends, and provided with hinged bars for tying across the split portions when these are opened out.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

SEPTEMBER 5.—Mr. P. Everitt in the chair.

Mr. A. M. Hastings showed a lens by Taylor, of Leicester, intended for detective camera purposes. It was fitted with an iris diaphragm and with Shew's spring shutter. A photograph illustrating the power of the instrument was also shown.

Mr. FRIESE GREENE then exhibited some photographs printed upon what he termed opal cards, also some printed upon sheets of white celluloid shaped and embossed in ornamental fashion with a raised flat space for the portrait. The printing was done by means of a gelatino-bromide emulsion, and the process of printing, developing, and fixing was demonstrated to the meeting, the exposure being made with a gas flame at a distance of about fifteen inches, for a time of from three to five seconds. Mr. Greene also read the following paper, dealing with the process and with some other photographic topics:—
